16

17 **Key Points:**

- 18 • The mean temperature in the high latitude MLT region is obtained by binning the SABER
19 observations based on yaw cycles during 2002–2023
- 20 • In the high latitude MLT, the cooling trend is seasonal symmetric and reaches peak of ≥ 6
21 K/decade at highest latitudes around summer solstice
- 22 • The trends of mesopause temperature depend on latitudes but are mostly negative and have
23 larger magnitudes at highest latitude

24

25

26 **Abstract**

27 The temperature trend in the mesosphere and lower thermosphere (MLT) region can be
28 regarded as an indicator of climate change. Using temperature profiles measured by the Sounding of
29 the Atmosphere using Broadband Emission Radiometry (SABER) instrument during 2002–2023
30 and binning them based on yaw cycle, we get continuous dataset with wide local time coverage at
31 50°S–80°N or 80°S–50°N. The seasonal change of temperature, caused by the forward drift of
32 SABER yaw cycle, is removed by using the climatological temperature of MSIS2.0. The corrected
33 temperature without any waves and is regarded as the mean temperature. At 50°S–50°N, the cooling
34 trends of the mean temperature are significant in the MLT region and are in agreement with
35 previous studies. The novel finding is that the cooling trends of ≥ 2 K/decade exhibit seasonal
36 symmetric and reach peaks of ≥ 6 K/decade at highest latitudes around the summer solstice.
37 Moreover, there are warming trends of 1–2.5 K/decade at pressure height range of 10^2 – 10^3 hPa,
38 specifically at latitudes higher than 55°N in October and December and at latitudes higher than
39 55°S in April and August. The mesopause temperature (height) in the northern summer polar region
40 is colder (lower) than that in the southern counterpart by ~ 5 –11 K (~ 1 km) over the past 22 years.
41 The trends of the mesopause temperature are dependent on latitudes and months. But they are
42 negative at most latitudes and reach larger magnitudes at highest latitudes. These results indicate
43 that the temperature in high latitude MLT region is more sensitive to dynamic changes.

44

45 **1 Introduction**

46 Observational and simulation studies have revealed that the global mean temperature trend is
47 cooling in the mesosphere and lower thermosphere (MLT) (Beig et al., 2003; Laštovička et al.,
48 2006; Yue et al., 2019b; Laštovička, 2023). The cooling trends observed in the MLT region are
49 mainly caused by the increasing anthropogenic greenhouse gases such as carbon dioxide. Moreover,
50 changes of the stratospheric ozone depletion and recovery, increasing mesospheric water vapor
51 concentration, solar and geomagnetic variations may also contribute to the long-term changes of
52 temperature in the MLT region (Laštovička, 2009; Yue et al., 2019a, 2015; Garcia et al., 2019;
53 Mlynczak et al., 2022; Zhang et al., 2023).

54 A recent review work by Laštovička (2023) summarized that temperature trends are generally
55 cooling but also depend on local times, heights, and geographic locations in the MLT region
56 (Venkat Ratnam et al., 2019; Das, 2021; She et al., 2019; Yuan et al., 2019; Ramesh et al., 2020).
57 These results were mostly derived from ground-based and satellite observations at low and middle
58 latitudes, while the simulations provided insights into the long-term trends from pole to pole. On the
59 other hand, the long-term trends in temperature at high latitudes have not been thoroughly examined
60 and well understood yet, due to scarce observations. Driven by the summer-to-winter meridional
61 circulation, the upwelling causes adiabatic cooling in the summer polar mesosphere, while the
62 downwelling causes adiabatic warming in the winter polar mesosphere (Dunkerton, 1978; Garcia
63 and Solomon, 1985). Thus, the high latitude temperature is more sensitive to the changes of
64 dynamics, wave and forcing, stratospheric wind etc. (Russell et al., 2009; Qian et al., 2017; Yu et
65 al., 2023).

66 The progress in studying long-term trends in the MLT region has been summarized and
67 reported by Laštovička and Jelínek (2019) and Laštovička (2023). Here we highlight some studies
68 related to trends in temperature at high latitudes. Using temperature measured by the Sounding of
69 the Atmosphere using Broadband Emission Radiometry (SABER) instrument and simulated by
70 Whole Atmosphere Community Climate Model version 4 (WACCM4), Garcia et al. (2019) showed
71 that the global mean SABER temperature (52°S–52°N) of a cooling trend of 0.4–0.5 K/decade
72 during 2002–2018 in the stratosphere and mesosphere, were smaller than those simulated by
73 WACCM4 (0.6–0.9 K/decade) but within 2 times of the standard deviation. Using Leibniz Institute
74 Middle Atmosphere Model (LIMA) under northern hemispheric conditions during 1871–2008,
75 Lübken et al. (2018) showed that the cooling trend in the MLT region was 1.5 K/decade during
76 1960–2008, and was 0.7 K/decade during 1871–2008 at 55–61°N on geometric heights. However,
77 the trend was neglectable on pressure heights. On pressure heights, the global mean SABER
78 temperature (55°S–55°N) had cooling trends of 0.5 and 2.6 K/decade, respectively, at 10^{-3} hPa (~92
79 km) and 10^{-4} hPa (~106 km) during 2002–2021 (Mlynczak et al., 2022). The results of Lübken et al.

80 (2018) and Mlynczak et al. (2022) illustrated that the cooling trends were larger over recent decades
81 on both geometric and pressure heights as compared to the beginning of industrialization. To
82 achieve a longer time series, Li et al. (2021) constructed a nearly 30-year dataset at 45°S–45°N by
83 merging the temperature measured by the Halogen Occultation Experiment (HALOE) instrument
84 during 1991–2005 and the SABER instrument during 2002–2019. They showed that the cooling
85 trend was significant and reached a peak of 1.2 K/decade at 60–70 km in the Southern Hemisphere
86 (SH) tropical and subtropical region. Moreover, the cooling trend in the SH was larger than its
87 counterpart in the Northern Hemisphere (NH).

88 At high latitudes, ground-based observations of OH nightglow rotational temperature revealed
89 a significant cooling trend of 1.2 ± 0.51 K/decade at Davis (68°S, 78°E) during 1995–2019 (French
90 et al., 2020). The OH rotational temperature around midnight exhibited a significant cooling trend
91 of $2.4 \text{ K} \pm 2.3/\text{decade}$ in summer and an insignificant cooling trend of $0.4 \pm 2.2 \text{ K}/\text{decade}$ in winter
92 at Moscow (57°N, 37°E) during 2000–2018 (Dalin et al., 2020). Using the ice layer parameters
93 simulated by the LIMA model and the Mesospheric Ice Microphysics And transport ice particle
94 model, Lübken et al. (2021) showed that the negative trend of noctilucent clouds heights (~83 km)
95 was primarily caused by CO₂-induced cooling at lower heights during 1871–2008 at 58°N, 69°N,
96 and 78°N. At these three latitudes, the cooling trends were of ~0.2 K/decade during 1871–1960 and
97 1.0 K/decade during 1960–2008. Near the latitude band of 64–70°N in June and 64–70°S in
98 December, Bailey et al. (2021) constructed two datasets by merging the temperature measured by
99 HALOE and SABER and by HALOE and SOFIE (Solar Occultation for Ice Experiment). They
100 showed that there were cooling trends of ~1–2 K/decade near 0.1–0.01 hPa (~68–80 km) and
101 warming trends of ~1 K/decade near 0.005 hPa (~85 km) at 64–70°N in June and 64–70°S in
102 December. Moreover, the WACCM-X simulation results by Qian et al. (2019) showed that the
103 temperature trends were mostly cooling in the MLT region. However, there were also warming at
104 ~80–95 km in the SH polar region from November to February (Fig. 3 of their paper). The
105 disagreement of these results at high latitudes might attribute to the different temporal spans and
106 local times, observations using different instruments, and different methods deriving the trends. It is
107 overarching to study the temperature trends at high latitudes using one coherent measurement over a
108 long period.

109 The SABER temperature profiles cover latitudes of 53°S–83°N in the north viewing
110 maneuvers and 83°S–53°N in the south viewing maneuvers since 2002. Each temperature profile
111 covers a height range of ~15–110 km with accuracies of ~1.8–2.3 K at $z=60\text{--}80$ km and ~5.4–8.4 K
112 at 90–100 km and vertical resolution of 2 km (Remsberg et al., 2008; Rezac et al., 2015). These data
113 exhibited remarkable stability over the last two decades following the correction of algorithm
114 instability (Mlynczak et al., 2020, 2022, 2023). Using the SABER temperature profiles during

115 2002–2019, Zhao et al. (2020) employed a 60-day moving window to obtain the mean temperature.
116 Their analysis revealed that the annual and global mean trend of mesopause temperature is cooling
117 with magnitude of 0.75 K/decade. Moreover, the cooling trend is significant in non-summer seasons
118 but insignificant in summer (May–August) at 60–80°N/S. It should be noted that, SABER yaw
119 cycle (YC) drifted forward about one month from 2002 to 2023 (see Fig. 1 below) due to changing
120 satellite orbit. This induces the local time (LT) coverage in a certain month differing from year to
121 year at high latitudes if the window is set to be constantly 60days.

122 Here we focus on the trend of the mean temperature without any atmospheric waves (i.e.,
123 gravity waves, tides and planetary waves). Calculating zonal mean can remove gravity waves,
124 nonmigrating tides and long-period planetary waves. However, migrating tides depend on LT and
125 are strong in the MLT region. They cannot be simply removed by calculating zonal mean. In this
126 work, we bin the data based on YC, which covers an interval of 54–64 days (see Fig. 1 below) and
127 provides almost full local time coverage (except the 1–3 hours around noon). Thus, the mean
128 temperature can be accurately determined by removing the migrating tides at 53°S–83°N or 83°S–
129 53°N using harmonic fitting. Each YC at every year covers varying ranges of dates. This results in
130 the aliasing of the seasonal variation of temperature into the mean temperature of each YC. This
131 issue can be resolved as below. We use the temperature of the recently released whole-atmosphere
132 empirical model MSIS2.0 (Emmert et al., 2021) as a reference for the seasonal variation. This
133 seasonal variation (more than 10 K as seen in Fig. 2b) embedded in YC drift is removed from the
134 mean temperature of each YC. Thus, using the advantages of SABER measurements at high
135 latitudes and binning the data based on YC, we focus on the long-term trends of the mean
136 temperature and the mesopause in the high latitude MLT region.

137 2 Method of calculating mean temperature and trend

138 The mean temperature (\bar{T}_{bk}) excludes gravity wave, tides and planetary waves. Moreover,
139 compared to the magnitudes of \bar{T}_{bk} , its trend is a small value and should be determined with extra
140 caution. The method of calculating \bar{T}_{bk} is based on a YC window. This ensures a good LT coverage
141 at high latitudes. Compared to the fixed 60-day window, the advantage and necessity of the YC
142 window are described below.

143 The YC window is defined as the temporal interval during which the SABER measurements
144 are in the northward or southward viewing maneuver. Figure 1 shows the beginning date and
145 temporal span of each YC. We see that there are about six YCs in each year, being named as YC1–
146 YC6. The temporal spans of YCs are 54–64 days. This ensures that the LT coverage of SABER
147 samplings is more than 18 hours at high latitudes. Therefore, migrating tides can be removed
148 efficiently through harmonic fitting. In contrast, the LT coverage in a fixed 60-day window is

149 different from year to year at high latitudes. This is because the temporal span of each YC drifted
 150 forward about one month from 2002 to 2023 (Fig. 1). For the case of the fixed 60-day window and
 151 at 70°N and in March (spanning from 14th February to 14th April with a center on 15th March), the
 152 sampling hours distributed at 0–2, 5–11, and 21–24 LT and had a coverage of only 14 hours in
 153 2005. However, the sampling hours in 2022 distributed at 0–10 and 13–24 LT and had a coverage of
 154 22 hours. The year-to-year variations of LT distribution and coverage might induce uncertainties
 155 and biases into \bar{T}_{bk} . Thus, the YC dependent window is necessary to obtain a wide LT coverage.

156 We note that the forward drift of YC raises an issue that each YC at every year covers varying
 157 ranges of date. This aliases seasonal variation of temperature into \bar{T}_{bk} and should be removed to get
 158 a corrected mean temperature (\bar{T}_{bcrt}). The detailed procedure of the calculating \bar{T}_{bcrt} and its trend is
 159 presented in Sec. 2.1–2.3. The procedure of calculating mesopause temperature and height is
 160 presented in Sec. 2.4.

161

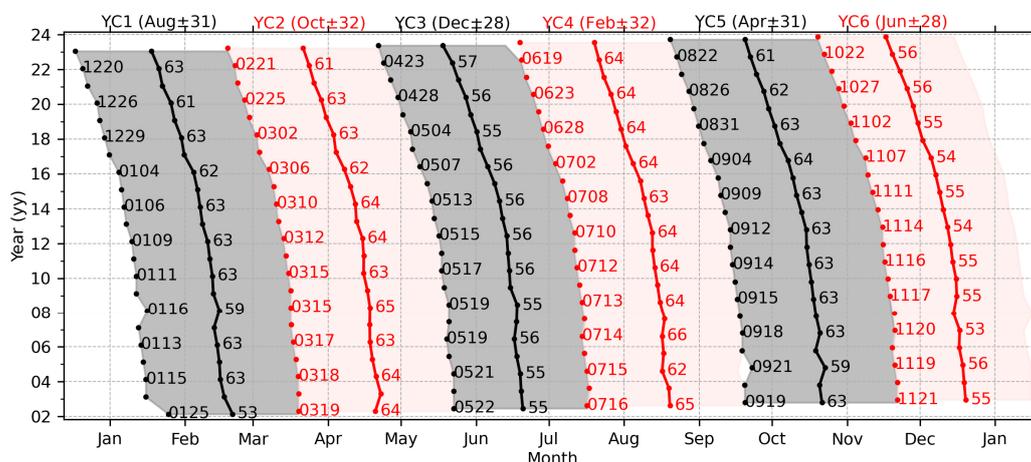

Figure 1. The temporal span of each YC from 2002 to 2023. The gray (red) region indicates the north (south) viewing maneuver. The beginning date (format of “mmdd”, “mm” and “dd” mean the month and the day of month, respectively) and temporal span (unit of days) of each yaw are labeled on the right of beginning (dot) and center date (dot-line), respectively. The six YCs and their center date in 2003 and half spans and are labeled as YC1–YC6 on the top.

162

163 2.1 Removing waves from SABER temperature

164 In each YC, the background temperature is calculated at three steps. Firstly, at each latitude
 165 band and pressure level, the daily zonal mean temperature (\bar{T}_d) is calculated by averaging the
 166 temperature profiles at ascending and the descending nodes, respectively. This largely removes the
 167 gravity waves, non-migrating tides, and long-period planetary waves. Here each latitude band has a

168 width of 10° with centers offset by 5° from 80°S to 80°N . Secondly, linear regression is performed
169 on \bar{T}_d at each node and is formulated as,

$$170 \quad \bar{T}_d = \bar{T}_{d0} + kt_{UT}. \quad (1)$$

171 Here, \bar{T}_{d0} is the mean temperature in each YC. t_{UT} is the universal time with a unit of day, k
172 represents the linear variation of \bar{T}_d in each YC. After removing the linear variation (kt_{UT}) from
173 \bar{T}_d , we get a residual temperature \bar{T}_{res} of each YC. Thirdly, tidal fitting is performed on \bar{T}_{res} of both
174 nodes and is formulated as,

$$175 \quad \bar{T}_{res} = \bar{T}_{bk} + \sum_{n=1}^3 a_n \cos(n\omega t_{LT} - \varphi_n). \quad (2)$$

176 Here, $\omega = 2\pi/24$ is the rotation frequency of Earth with a unit of rad/hour, t_{LT} is the local time
177 with a unit of hour, a_n and φ_n are, respectively, the amplitude and phase of migrating diurnal ($n =$
178 1), semidiurnal ($n = 2$) and terdiurnal ($n = 3$). Now, \bar{T}_{bk} excludes atmospheric waves and is
179 regarded as the mean temperature.

180 2.2 Removing seasonal variations from the mean temperature

181 Figure 1 shows that the center date of each YC shifts forward about one month from 2002 to
182 2023. This forward drift induces the seasonal variation of temperature into \bar{T}_{bk} . This could further
183 alias the long-term trend calculated from \bar{T}_{bk} and can be removed with the help of MSIS2.0. This is
184 because MSIS2.0 has assimilated the SABER temperature profiles during 2002–2016. The
185 climatological temperature of MSIS2.0 coincides with that of SABER within the uncertainties of \sim
186 3 K in the MLT region (Emmert et al., 2021). The detailed procedure of removing seasonal
187 variations is described below.

188 Firstly, we calculate the mean temperature of MSIS2.0. The temperature profiles (at 15
189 longitudes and 24 LTs each day) are calculated from MSIS2.0 under the conditions of lower solar
190 activity ($F_{10.7} = 50\text{ SFU}$) and geomagnetic quiet time ($ap = 4\text{ nT}$) throughout one calendar year.
191 Such that solar and geomagnetic activities do not influence the seasonal variation and trend of the
192 mean temperature. Then the daily zonal mean is performed on temperature profiles of each day.
193 This removes tides and long-period planetary waves. The daily zonal mean temperature in each YC
194 is averaged to get the mean temperature (\bar{T}_{MSIS}^{year} , the superscript means the YC in that year). Figures
195 2(a1) and (a2) show the \bar{T}_{MSIS}^{year} at 70°N in YC3 and 70°S in YC6 during 2002–2023, respectively.

196 Secondly, we calculate the seasonal variations of each YC. The seasonal variations ($\Delta\bar{T}_{MSIS}^{year}$)
197 caused by the forward drift of each YC in different years are quantified by the difference between
198 \bar{T}_{MSIS}^{year} of that year and the reference year (i.e., \bar{T}_{MSIS}^{2002}). For example, the difference between 2003
199 and 2002 is calculated as $\Delta\bar{T}_{MSIS}^{2003} = \bar{T}_{MSIS}^{2003} - \bar{T}_{MSIS}^{2002}$. More specifically, since \bar{T}_{MSIS}^{year} does not include
200 the year-to-year variations of temperature but depends on the temporal span of YC only, $\Delta\bar{T}_{MSIS}^{2003}$ in
201 YC3 represents the seasonal variation from 20th to 19th June. Figures 3(b1) and (b2) show $\Delta\bar{T}_{MSIS}^{year}$ at

202 70°N in YC3 and 70°S in YC6 during 2002–2023, respectively. It is evident that the forward drift of
 203 YC induces temperature variations of ± 20 K at 70°N/S from 2002 to 2023, and should be removed
 204 before we determine the long-term trends in SABER temperature.
 205

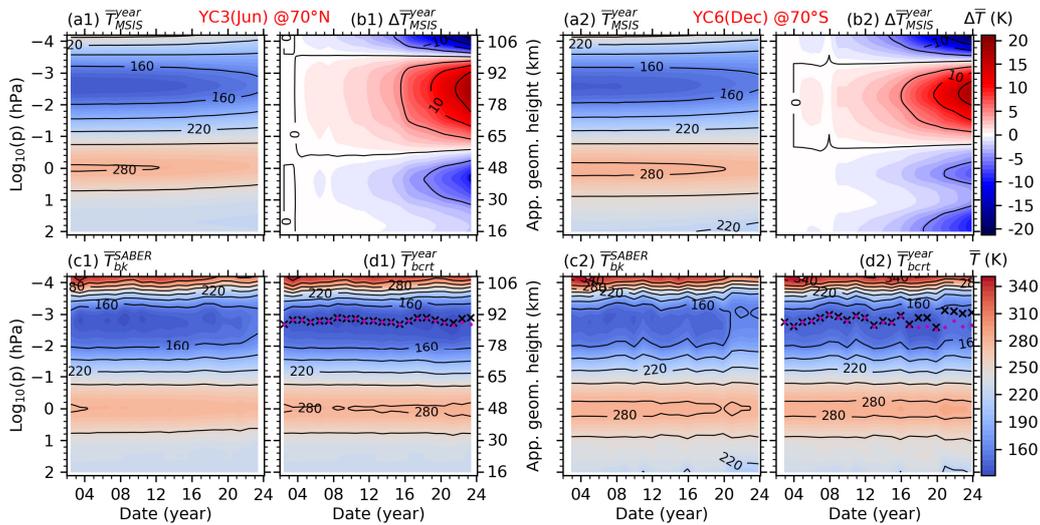

Figure 2. The date-height distributions of the mean temperature calculated from NRLMSIS 2.0 (\bar{T}_{MSIS}^{year}) and SABER (\bar{T}_{bk}^{year}) at 70°N in YC3 (left two columns) and 70°S in YC6 (right two columns). \bar{T}_{MSIS}^{year} is used as a reference to calculate the seasonal variation ($\Delta\bar{T}_{MSIS}^{year}$) caused by the forward drift of YC from 2002 to 2023. Then, the corrected mean temperature (\bar{T}_{bcrt}^{year}) is calculated by removing $\Delta\bar{T}_{MSIS}^{year}$ from \bar{T}_{bk}^{year} . The mesopause heights calculated from \bar{T}_{MSIS}^{year} and \bar{T}_{bcrt}^{year} are plotted as black cross and red dots, respectively. The plots of \bar{T}_{MSIS}^{year} , \bar{T}_{bk}^{year} , and \bar{T}_{bcrt}^{year} have the same colorbar of \bar{T} . The plot of $\Delta\bar{T}_{MSIS}^{year}$ has the colorbar of $\Delta\bar{T}$. Same scales in y-axis are used in all panels. The approximate geometric height is label on the right of the second column.

206

207 **Table 1.** The date range of each YC and its corresponding season in the reference year

YCs	YC1	YC2	YC3	YC4	YC5	YC6
Date range	20/Feb \pm 31	20/Apr \pm 32	20/Jun \pm 28	19/Aug \pm 32	13/Oct \pm 31	10/Dec \pm 28
Season	later winter	later spring	summer	early autumn	later autumn	winter

208

209 Finally, we correct the mean temperature. The corrected mean temperature (\bar{T}_{bcrt}^{year} , shown in
 210 Figs. 3d1 and d2) is obtained by removing $\Delta\bar{T}_{MSIS}^{year}$ from \bar{T}_{bk}^{year} . This removes the seasonal variation
 211 caused by the forward drift of YC from 2002 to 2023. Moreover, \bar{T}_{bcrt}^{year} retains the long-term trend
 212 of the mean temperature. We note that, after removing $\Delta\bar{T}_{MSIS}^{year}$, \bar{T}_{bcrt}^{year} covered by each YC can be

213 represented by its center date and half span in the reference year (Tab. 1). Table 1 also lists the
214 approximate season related to each YC.

215

216 **2.3 Determining the long-term trend of the mean temperature**

217 To calculate accurate trends in the MLT region, multi-year variations should be removed
218 properly. The multi-year variations of temperature in the MLT region could be the solar cycle with a
219 period of about 11 years (Beig et al., 2008; Tapping, 2013; Forbes et al., 2014; Gan et al., 2017;
220 Qian et al., 2019), and the influences from below, such as the stratospheric quasi-biennial oscillation
221 (QBO) with a period of about 28 months (Baldwin et al., 2001; Zhao et al., 2021) and El Niño-
222 Southern Oscillation (ENSO) with varying cycles of around 2–7 years (Domeisen et al., 2019; Li et
223 al., 2013, 2016; Randel et al., 2009). The solar cycle can be represented by the solar radiation flux
224 at 10.7 cm (i.e., $F_{10.7}$ with unit of $\text{SFU}=10^{-22}\text{Wm}^{-2}\text{Hz}^{-1}$) (Tapping, 2013). ENSO is represented by
225 multivariate ENSO index (MEI) (Domeisen et al., 2019). QBO is represented by the monthly mean
226 zonal wind measured by radiosonde at Singapore (Baldwin et al., 2001). The multiple linear
227 regression (MLR) method is effective to separate the long-term trend in temperature from solar
228 cycle, ENSO and QBO. The MLR equation is formulated as,

$$229 \quad Y(t) = c_0 + c_1t + c_2F_{10.7}(t) + c_3\text{ENSO}(t) + c_4\text{QBO}_{10}(t) + c_5\text{QBO}_{30}(t) + \varepsilon(t). \quad (3)$$

230 Here, Y represents the mean temperature at year t from 2002 to 2023. c_0 represents a mean state of
231 Y . c_1 is the long-term trend of Y . c_2, c_3, c_4, c_5 represent the contributions from solar cycle, ENSO,
232 and QBO zonal wind at 10 hPa (QBO_{10}) and 30 hPa (QBO_{30}), respectively. The terms of $F_{10.7}$,
233 ENSO, QBO_{10} , and QBO_{30} are included in Eq. (3) for the purpose of determining long-term trend
234 correctly but are not considered further in this work.

235 The statistical significances of the regression coefficients are measured by the student-t test
236 and the variance-covariance matrix of Eq. (3). Specifically, in Eq. (3), the sampling points are 22,
237 and the predictor variables are 6. This results in the degree of freedom of 16. Consequently, the
238 critical value is ~ 2.1 based on the student-t test at confidence level of 95% (Kutner et al., 2005).
239 This signifies that, with reference to the 95% confidence level, the magnitude of the regression
240 coefficient should be at least 2.1 times greater than the standard deviation.

241 **2.4 Determining the mesopause of each yaw cycle**

242 The mesopause temperature (\bar{T}_{msp}) is defined as the minimum of the mean temperature. The
243 pressure level where the minimum temperature occurs is defined as the mesopause height (z_{msp}).
244 Figures 2(d1) and (d2) show the mesopause heights calculated from \bar{T}_{bk}^{year} (black cross) and \bar{T}_{bcr}^{year}
245 (red dot), respectively. We see that the mesopause heights calculated from \bar{T}_{bk}^{year} and \bar{T}_{bcr}^{year} are
246 nearly identical in the first several years but exhibit discrepancies over the later several years. This

247 implies that the seasonal variation caused by the forward drift of YC affects the mesopause heights
 248 to some extent. Moreover, the mesopause heights exhibit larger variabilities in the southern summer
 249 polar region (YC6) than that in the northern summer polar region (YC3). Figure 3 shows the date-
 250 latitude distributions of the mesopause temperature (\bar{T}_{msp}) and height (z_{msp}) calculated from
 251 \bar{T}_{bcrt}^{year} . We note that z_{msp} is defined on pressure level initially (Fig. 2d). To compare with previous
 252 studies, z_{msp} is interpolated onto the geometric heights in Fig. 3.
 253

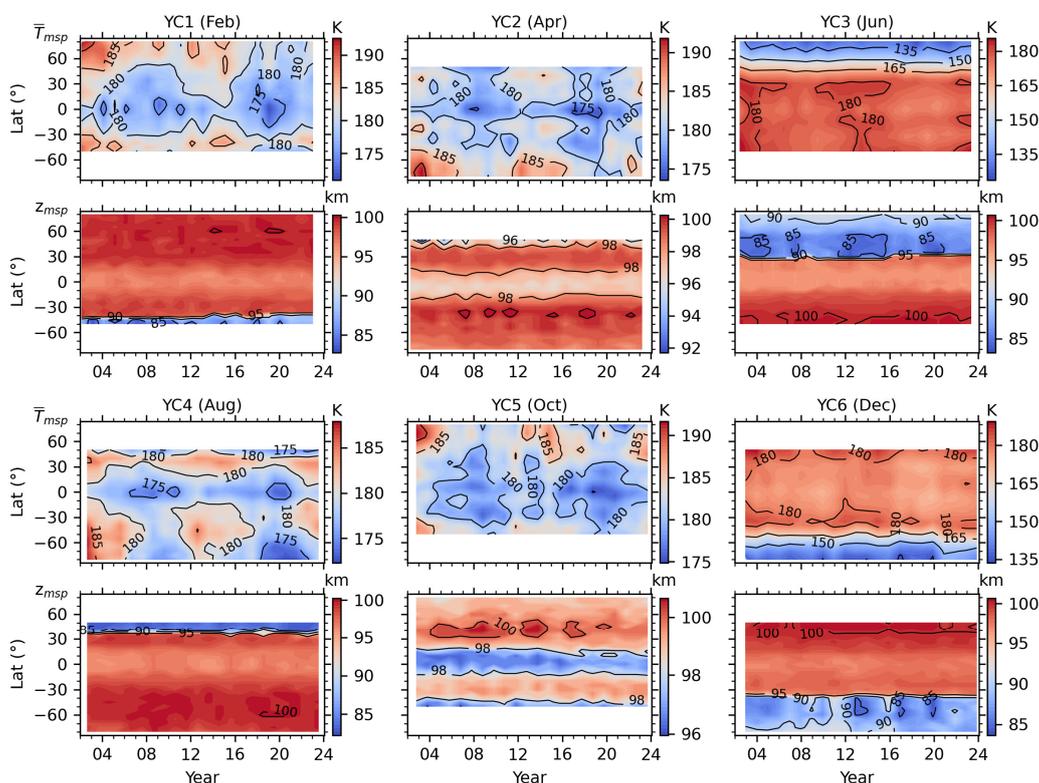

Figure 3. The date-latitude distributions of the mesopause temperature (\bar{T}_{msp} , the first and third rows) and height (z_{msp} , the second and fourth rows) calculated from \bar{T}_{bcrt}^{year} of each YC from 2002 to 2023. Here z_{msp} is interpolated from pressure level to geometric height.

254

255 Previous SABER studies often discarded high latitudes possibly due to insufficient LT
 256 coverage that induces uncertainties in the mean temperature estimation. A major advantage of
 257 binning the SABER temperature based on YC is that an accurate mean temperature can be obtained.
 258 Such that the latitude variations of \bar{T}_{msp} and z_{msp} at high latitudes can be thoroughly studied.
 259 Firstly, we focus on the YCs in northern summer and winter (i.e., YC3 and YC6) because the
 260 summer mesopause at high latitudes is more sensitive to the summer-to-winter circulation

261 (Dunkerton, 1978; Qian et al., 2017). In YC3 (YC6), \bar{T}_{msp} and z_{msp} decrease from 50°S to 80°N
262 (from 50°N to 80°S) in general. We note that \bar{T}_{msp} has local minima around the Equator throughout
263 the 22 years in YC3 and YC6 and is the coldest at the highest latitudes of the summer hemisphere.
264 z_{msp} is the lowest at 40–60°N/S throughout the 22 years. Besides the latitude variations, \bar{T}_{msp} and
265 z_{msp} also exhibit multi-year variations. For example, \bar{T}_{msp} is colder around the Equator during the
266 solar minima (i.e., 2007–2008, 2019–2021) in YC3 and YC6. In YC6, the lower z_{msp} at the
267 southern higher latitudes might be related to the warm phase of ENSO during 2002–2005 and
268 2016–2019.

269 In YC2 and YC5, the latitude variations of \bar{T}_{msp} and z_{msp} are almost hemispheric symmetry.
270 \bar{T}_{msp} is the coldest around the Equator and the warmest at the highest latitudes. z_{msp} is the lowest
271 at lower latitudes and the highest at the highest latitudes. In YC1, \bar{T}_{msp} and z_{msp} share the similar
272 latitude variations in winter (YC6). The difference is that \bar{T}_{msp} is warmer in YC1 than that in YC6.
273 z_{msp} is higher in YC1 than that in YC6. In YC4, \bar{T}_{msp} and z_{msp} share the similar latitude variations
274 in summer (YC3). The difference is that \bar{T}_{msp} is warmer in YC4 than that in YC3. z_{msp} is higher in
275 YC4 than that in YC3. In YC1–2 and YC4–5, multi-year variations of \bar{T}_{msp} exhibit clear solar cycle
276 dependence. At lower latitudes, \bar{T}_{msp} are colder during the solar minima (i.e., 2006–2010, 2017–
277 2021). At high latitudes, \bar{T}_{msp} are warmer during the solar maxima (i.e., 2002–2005, 2012–2014,
278 and after 2021). However, it looks like that the multi-year variations of z_{msp} are not as obvious as
279 those of \bar{T}_{msp} . These multi-year variations are considered in Eq. (3) to separate the long-term trend
280 in \bar{T}_{msp} correctly but are not considered further in this work.

281 **3 Trends of temperature in the MLT region and mesopause**

282 **3.1 Trends of temperature in the MLT region**

283 Trends of the corrected mean temperature and their significances of each YC are shown in Fig.
284 4. These trends are generally larger at high latitudes than those at lower latitudes within the six YCs.
285 Moreover, the trends show both hemispheric symmetry and asymmetry approximately in the high
286 latitude MLT region.

287 First, we describe the hemispheric symmetry in the trends. In YC1 and YC4 and above 10^{-3}
288 hPa, the cooling trends are ≥ 2 K/decade at latitudes higher than 40°N (YC1) and 40°S (YC4),
289 respectively. Around 10^{-4} hPa, the cooling trends reach their peaks of ≥ 6 K/decade. In addition,
290 there are also warming trends of ≥ 2 K/decade at latitudes higher than 30°S (YC1) and 30°N (YC4),
291 respectively. Above mesopause, there are cooling trends of ≥ 2 K/decade observed within the latitude
292 range of 20–50°S for YC5 and 20–50°S for YC2. Additionally, in the region just below 10^{-3} hPa,
293 there are warming trends of ≥ 2 K/decade at latitudes of 50–80°N for YC5 and 50–80°S for YC2. In

294 YC3 and YC6, the cooling trends of ≥ 2 K/decade shift upward from the mesopause at 80°N (YC3)
295 and 80°S (YC6) to 10^{-4} hPa at 50°S (YC3) and 50°N (YC6). There are also cooling trends of ≥ 6
296 K/decade at high latitudes of summer hemisphere. Meanwhile, the coldest trends are ≥ 10 K/decade
297 just below 10^{-4} hPa and at 80°N/S . Although the cooling trends in the MLT region have been
298 reported extensively at lower and middle latitudes (Beig et al., 2003; Laštovička, 2023), the extreme
299 cooling trends at high latitudes and above the summer mesopause have not been reported yet.
300

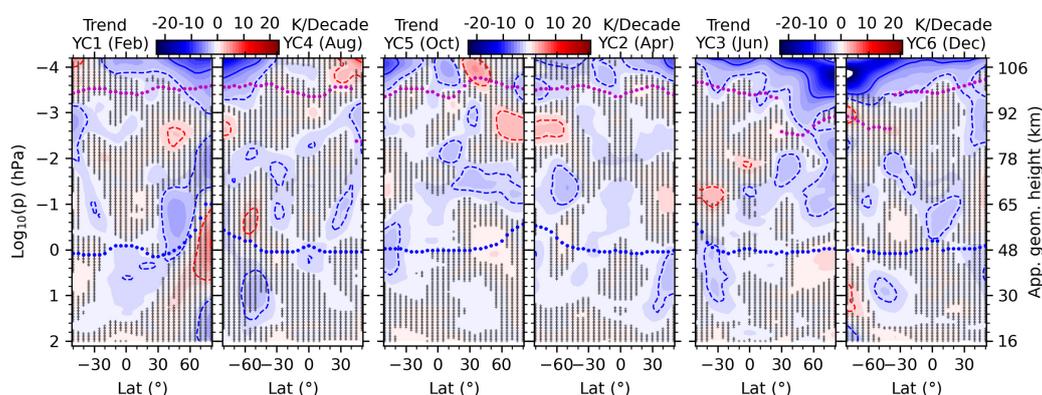

Figure 4. Trends of the corrected mean temperature in the six YCs. The solid and dashed contour lines indicate ± 6 and ± 2 K/decade, respectively. The red and green dots indicate the heights of the mesopause and stratopause, respectively. The regions marked by “+” indicate that trends are not significant with reference to the 95% the confidence level. The approximate geometric height is label on the last panel.

301

302 Next we describe the hemispheric asymmetry in the trends. In YC1 and YC4, the cooling
303 trends of ≥ 2 K/decade in YC1 extend to a wider latitude range (20°N – 80°S) than those in YC4
304 (30°S – 80°S) above 10^{-3} hPa. The insignificant warming trends of ≥ 2 K/decade can be seen in the
305 stratosphere at latitudes higher than 60°N in YC1 but at 45 – 60°S in YC4. In YC5 and YC2, the
306 cooling trends of ≥ 2 K/decade can be seen around the stratopause at 30 – 50°S (YC5) but below the
307 stratopause at 30 – 50°N (YC2). In YC3 and YC6, the significant warming trends of ≥ 2 K/decade in
308 YC6 are stronger than those in YC3 around 0.1 hPa. In addition, the warming trends near the
309 summer mesopause are significant in YC6 but insignificant in YC3. The simulation results in Qian
310 et al. (2019) also demonstrated warming trends in the southern summer MLT region. Specifically,
311 they showed significant warming trends below ~ 95 km and cooling trends above ~ 95 km at
312 latitudes exceeding 45°S between November and February. In contrast, there were insignificant or
313 warming trends at latitudes exceeding 45°N during June and July. Qian et al. (2019) attributed the
314 warming trend in the summer mesosphere to the changing meridional circulation.

315 **3.2 Structure and trends of the mesopause**

316 Taking advantages of the continuous measurements over a long-term (22 years or equivalently
 317 two solar cycles), and YC binning at 50°S–80°N or 80°S–50°N, the robust mean states of the
 318 mesopause temperature (\bar{T}_{msp}) and height (z_{msp}), as well as their trends and responses of \bar{T}_{msp} to
 319 solar cycle, ENSO, QBO are quantified using MLR. Here we focus on the mean states and trends of
 320 the mesopause temperature and height.

321

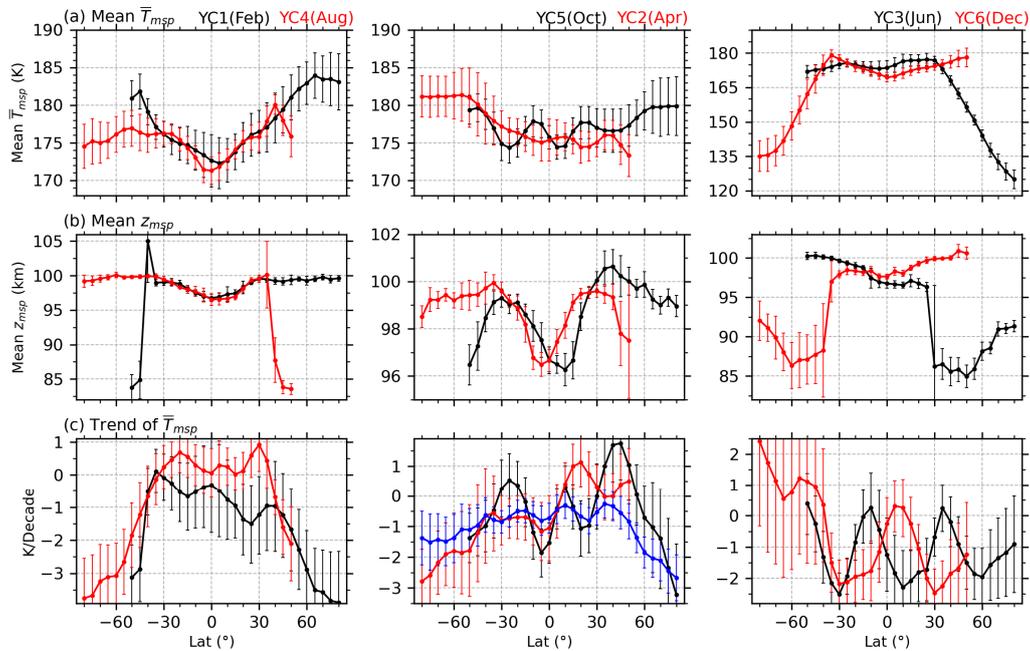

Figure 5. Latitude variations of the means of the mesopause temperature (\bar{T}_{msp} , a) and height (z_{msp} , b) and the trends of \bar{T}_{msp} (c) of the six YCs. The error bar of each YC indicates 2.1 times standard deviation (i.e., at 95% confidence level according to the student-t test). The all-YC mean trend of mesopause temperature is shown as a blue line in the middle panel of (c).

322

323 Figures 5(a) and 7(b) show the mean \bar{T}_{msp} and z_{msp} over 22 years of the six YCs. In YC1–2
 324 and YC4–5, the mean \bar{T}_{msp} is in the range of 172–183 K but is warmer at latitudes higher than 40°N
 325 (YC1) and 40°S (YC2) those in the counterparts of YC4 and YC5. The mean z_{msp} is mainly in the
 326 range of ~96–102 km but is higher than ~85 km at 40–50°N (YC1) and 40–50°N (YC4). In YC3,
 327 the mean \bar{T}_{msp} decreases sharply with latitudes from ~180 K at 30°N to ~125 K at 80°N. The mean
 328 z_{msp} in YC3 reaches a minimum of ~85 km at 60°N. In YC6, the mean \bar{T}_{msp} decreases sharply with
 329 latitudes from ~180 K at 35°S to ~135 K at 80°S. The mean z_{msp} in YC6 reaches a minimum of

330 ~86 km at ~50°S. The mean \bar{T}_{msp} (z_{msp}) in the northern summer polar region is colder (lower) than
331 that in the southern counterpart by ~5–11 K (~1 km). The hemispheric asymmetries of the summer
332 mesopause temperature and height coincide with Xu et al. (2007), who used the SABER
333 temperature data during 2002–2006 and showed that the mean \bar{T}_{msp} in the summer polar region of
334 the NH is ~5–10 K colder than its counterpart in the SH. A recent study by Wang et al. (2022), who
335 used the SABER temperature data during 2002–2020, showed that the mean \bar{T}_{msp} in the summer
336 polar region of the NH is ~10 K colder than its counterpart in the SH. Moreover, the transition
337 latitudes of the mean \bar{T}_{msp} (z_{msp}) from higher temperature (height) are 30°N in YC3 and 40°S in
338 YC6. This coincides well with those reported by Xu et al. (2007) and Wang et al. (2022). These
339 hemispheric asymmetries of the mean \bar{T}_{msp} and z_{msp} , and the transition latitudes could be caused
340 by the hemispheric asymmetry of solar radiation and gravity wave forcing (Xu et al., 2007).

341 Figure 5c shows that trends of \bar{T}_{msp} in YC1 and YC4 are extreme cooling (≥ 2 K/decade) at
342 latitudes higher than 55°N/S. While at 40°S–40°N, trends of \bar{T}_{msp} in YC1 are cooling with
343 magnitudes of ~0–2 K/decade but are warming in YC4 with magnitudes of ~0–1 K/decade. In YC2
344 and YC5, trends of \bar{T}_{msp} are either cooling or warming, depending on the specific latitudes and
345 months being considered. At southern latitudes, trends of \bar{T}_{msp} are cooling with magnitudes of ≥ 1
346 K/decade in YC2. Trends of \bar{T}_{msp} in YC5 change sharply from 2.0 K/decade at 45°N to -3
347 K/decade at 80°N. In YC3 and YC6, trends of \bar{T}_{msp} are mainly cooling except the insignificant
348 warming trends in YC6 and at latitudes higher than 40°S. Although trends of \bar{T}_{msp} are warming at
349 some latitudes of certain YC, the all-YC mean trends of \bar{T}_{msp} (blue line in Fig. 5c) are cooling with
350 magnitudes of 0.3–1 K/decade at 50°S–50°N. At latitudes higher than 55°S, the insignificant
351 cooling trends are ≤ 1.5 K/decade. In contrast, at latitudes higher than 55°N, the significant cooling
352 trends are ≥ 1.5 K/decade.

353 4 Discussions

354 Laštovička & Jelínek (2019) pointed out that the temporal interval of data might influence the
355 long-term trend. Using the nocturnal temperature in the MLT region measured by lidars around
356 41°N and 42°N over the period of 1990–2017, She et al. (2019) demonstrated that the cooling
357 trends are ~2.0–4.5 K/decade over only one solar cycle and are ~2.0–2.5 K/decade if the data
358 length is longer than two solar cycles. Using the SABER temperature profiles during 2002–2019,
359 Zhao et al. (2020) showed that the significant trends of \bar{T}_{msp} and their responses to solar cycle can
360 be obtained at 50°S–50°N over longer than one solar cycle. Both She et al. (2019) and Zhao et al.
361 (2020) showed that the trends are relatively insensitive to the specific beginning and ending time of
362 the data as compared to the data length. Since the data length used in this study spans approximately

363 two solar cycles, the derived trends are highly reliable.

364 **4.1 The reliability of trends in the MLT region**

365 To facilitate a comparison with previously reported the annual and global-mean trends in the
366 MLT region, we present the mean trends of the corrected mean temperature at 50°S–50°N and at
367 55–80°S or 55–80°N of the six YCs (Fig. 6). The mean trends at 50°S–50°N of each YC are cooling
368 with magnitudes of ~0.5–1 K/decade at 10–10⁻³ hPa. The exception is the warming trend of 0.2
369 K/decade around 10⁻² hPa in YC1 and of 0.1 K/decade around 4×10⁻³ hPa in YC3. At higher
370 heights, the cooling trends decrease sharply with height and reach to ~2 K/decade in YC5 and to ~3
371 K/decade in YC2 at 10⁻⁴ hPa. Compared to the situation in YC2 and YC5, the cooling trends
372 decrease more sharply with height in YC3 and YC6. Their magnitudes change nearly identically and
373 are from ~0.5 K/decade at 2×10⁻³ hPa to ≥5 K/decade at 10⁻⁴ hPa. When the mean trends at 50°S–
374 50°N across all-YC are further averaged, we obtain an annual mean trend (blue line in Fig. 5a). The
375 annual mean trend is cooling with magnitudes of ~0.5–0.8 K/decade and vary with height slightly at
376 10–5×10⁻⁴ hPa.

377 The height variation and the magnitude of the annual mean trend are similar to the previous
378 results (Garcia et al., 2019; Mlynczak et al., 2022; Zhao et al., 2021). Figure 3 of Garcia et al.
379 (2019) revealed that the global mean (52°S–52°N) SABER temperature trends are cooling with
380 magnitudes of ~0.5–0.9 K/decade at 10–5×10⁻⁴ hPa during 2002–2018. These magnitudes are
381 slightly smaller than those derived from WACCM. Table 1 of Mlynczak et al. (2022) demonstrated
382 that the global mean (55°S–55°N) SABER temperature also display cooling trends with magnitudes
383 of ~0.51–0.63 K/decade at 1–10⁻³ hPa. Similarly, Fig. 4 of Zhao et al. (2021) revealed that the
384 global mean (50°S–50°N) SABER temperature trends are cooling with magnitudes of ~0.5–0.9
385 K/decade at 30–105 km. At 10⁻⁴ hPa, the extreme cooling trend of 2.6 K/decade in Table 1 of
386 Mlynczak et al. (2022) is smaller than the 5 K/decade derived here (blue line in Fig. 6a). Further
387 examining the trends across the six YCs (Figs. 4 and 6a), it becomes evident that the extreme
388 cooling trend is mainly attributed to the middle latitudes of summer hemisphere (i.e., YC3 and
389 YC6) and partially from other months. As suggested by Mlynczak et al. (2022), the extreme cooling
390 trend at 10⁻⁴ hPa is due to a decrease in solar irradiance that is not captured by the $F_{10.7}$ index.

391 These detailed comparisons showed that the trends at pressure levels reported by Garcia et al.
392 (2019) and Mlynczak et al. (2022) support the height variations and magnitudes of the trends derived
393 here directly. Although the trends reported by Zhao et al. (2021) are in geometric height, their
394 height variations and magnitudes agree with the trends derived here, too. Thus, the method of
395 binning SABER samplings based on YC leads a reliable global mean trends at 50°S–50°N.
396 Moreover, this method provides an opportunity to study the trends at latitudes higher than 55°N/S in
397 certain months.

398

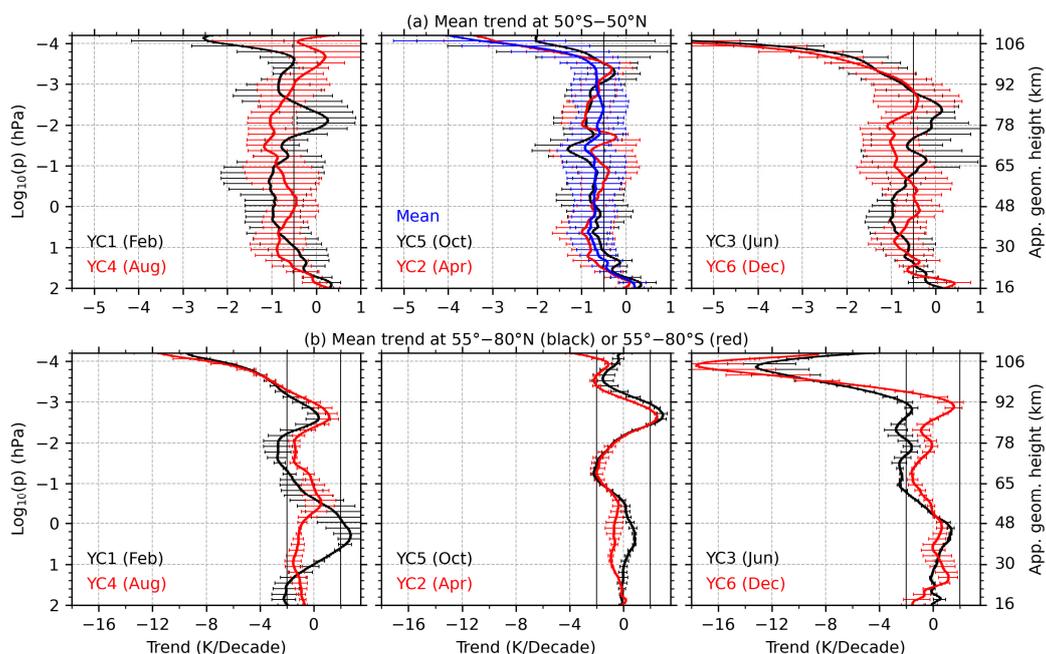

Figure 6. Mean trends of the corrected mean temperature at 50°S–50°N (a) and at 55–80°S (red line in b) or 55–80°N (black line in b) of the six YCs. The annual mean trend is calculated by averaging the trends of the six YCs at 50°S–50°N and is shown a blue line in the middle panel of (a). The error bars indicate standard errors of the averaged data.

399

400 At latitudes higher than 55°N/S, the height variations of the mean trends of the six YCs (Fig.
 401 6b) are seasonal symmetric approximately above 1 hPa. The magnitudes of trends are mainly in the
 402 range of -2–2 K/decade below the height of 10^{-3} hPa. An interesting feature is the warming trends of
 403 1–2.5 K/decade at 10^{-2} – 10^{-3} hPa in April, August, October, and December. The peaks of the
 404 warming trends vary from 4×10^{-3} hPa to 10^{-3} hPa in different months. Focusing on the latitude band
 405 of 64–70°N in June and 64–70°S in December, Bailey et al. (2021) merged the temperature data
 406 from HALO and SABER (total length of 29 years) and HALOE and SOFIE (total length of 22
 407 years). Their analysis revealed warming trends of 1–2 K/decade near 5×10^{-3} hPa (~85 km) at 64–
 408 70°N in June and 64–70°S in December, as illustrated in Fig. 7 of their paper. The results simulated
 409 by WACCM-X showed significant warming trends at ~80–95 km at latitudes higher than 45°S from
 410 November to February and close to zero or warming trends at latitudes higher than 45°N from June
 411 to July (Qian et al., 2019). The warming trends in December derived here coincides with those
 412 reported by Bailey et al. (2021) and Qian et al. (2019). The weak warming trend at 2×10^{-3} hPa in
 413 June coincides with those in Qian et al. (2021) but is much smaller than the 1–2 K/decade reported

414 by Bailey et al. (2021). In April and October, the warming trends are hemispheric symmetric at 10^3
415 $2\text{--}10^{-3}$ hPa and reach peak of ≥ 2 K/decade at 3×10^{-3} hPa. Above 10^{-3} hPa, the trends transit from
416 warming to cooling.

417 The extreme cooling trends at high latitudes of the summer hemispheres (YC3 and YC6) might
418 be resulted from the changing summer-to-winter circulation and gravity wave forcing in the MLT
419 region. The circulation is upwelling in the summer hemisphere and causes a cold summer
420 mesosphere through adiabatic cooling. Conversely, in the winter hemisphere, the circulation is
421 downwelling, leading to a warm winter mesosphere through adiabatic warming (Garcia and
422 Solomon, 1985). A necessary condition for the extreme cooling trends at summer high latitudes is
423 the stronger upwelling and thus the increasing gravity wave body force in the summer hemispheres.
424 Previous studies showed that the potential energy of gravity waves (GWPE) in the MLT region
425 exhibited significant positive trends at southern high latitudes in January and at northern high
426 latitudes in July (Fig. 5 of Liu et al., 2017). The positive trends of GWPE might enhance the
427 strength of upwelling and thus the extreme cooling trends at high latitudes of summer hemispheres.

428 **4.2 The reliability of the mesopause trends**

429 The trends of \bar{T}_{msp} derived in this study are significant and mainly negative at $50^\circ\text{S}\text{--}50^\circ\text{N}$
430 across most YCs. The averaged trend of \bar{T}_{msp} of the six YCs is -0.64 ± 0.22 K/decade over $50^\circ\text{S}\text{--}$
431 50°N . When the average is performed over $80^\circ\text{S}\text{--}80^\circ\text{N}$, the trend of \bar{T}_{msp} of the six YCs is $-$
432 1.03 ± 0.40 K/decade. The cooling trend of \bar{T}_{msp} derived here coincides also with the -0.5 ± 0.21
433 K/decade in the mesosphere (Garcia et al., 2019) within only $50^\circ\text{S}\text{--}50^\circ\text{N}$. Compared to the trend
434 derived from sodium lidar observations during nighttime only around 40°N , the trends of \bar{T}_{msp} from
435 SABER are about $-0.1, 0.0, -0.2, -0.8, 0.6, -1.9$ K/decade in the six YCs and have annual mean of $-$
436 0.4 K/decade. This is less than the significant cooling trend of $2.3\text{--}2.5$ K/decade during 1990–2018
437 but is consistent with the insignificant cooling trend of $0.2\text{--}1$ K/decade during 2000–2018 (Yuan et
438 al., 2019). The comparisons of \bar{T}_{msp} between our results and those from satellite, ground-based
439 observations exhibit general consistencies in the sense of annual mean or global-mean.

440 A notable feature is the warming trends of \bar{T}_{msp} with magnitudes of $0\text{--}2$ K/decade at latitudes
441 higher than 40°S in YC6. This warming trend is insignificant under 95% confidence level. If we
442 change the temporal interval from 2002–2023 to 2002–2019, the trends of \bar{T}_{msp} are cooling with
443 magnitudes of $1\text{--}2$ K/decade. Here we note that the year 2020 is just after the time when the
444 SABER temperature data was revised (version 2.08, since 15 December 2019) (Mlynczak et al.,
445 2023). In this work, we use the SABER temperature data of versions 2.07 (before 15 December
446 2019) and 2.08 (after 15 December 2019). According to Mlynczak et al. (2023), the new released
447 data are free from the algorithm instability. On the other hand, there is no significant difference in

448 the counterpart of YC3. A recent study by Yu et al. (2023) showed that the Hunga Tonga Hunga-
449 Ha'apai (HTHH) volcanic eruption on 15 January 2022 induced temperature anomalies of ± 10 K
450 globally in the stratosphere and mesosphere in August. The anomalies disappeared after September
451 2022. This indicates that the volcanic eruption may influence the mesosphere temperature through
452 circulations and waves. From the mesopause temperature of YC6 shown in Fig. 3, we see that the
453 warmer mesopause occurred after 2020 before the HTHH volcanic eruption. Thus, the largest
454 difference in YC6 may not be caused by the algorithm instability or the HTHH volcanic eruption but
455 a realistic result. As shown in Figs. 2(d) and 5(b) and reported by Wang et al. (2022), the annual
456 variability of z_{msp} is ~ 5 km at the southern high latitudes (YC6) but is relative stable at the northern
457 high latitudes (YC3). The large annual variability of z_{msp} induces a large variability of \bar{T}_{msp}
458 (indicated by large standard deviations in the right panel of Fig. 5b). This in turn contributes to the
459 large variability of the trends of \bar{T}_{msp} at southern high latitudes.

460 5 Summary

461 Using the temperature profiles measured by the SABER instrument throughout the period of
462 2002–2023 (about two solar cycles) and binning them based on yaw cycles (YCs), we get
463 continuous data with good LT coverage within the range of 50°S – 80°N or 80°S – 50°N . Then we can
464 obtain an accurate mean temperature excluding atmospheric waves. The temporal span of each YC
465 drifted forward about one month from 2002 to 2023, aliasing the seasonal change in temperature
466 into long-term trends. This season change is removed by using the climatological temperature of
467 MSISE2.0. The remaining temperature is regarded as the corrected mean temperature (\bar{T}_{bcrt}^{year}) of
468 each YC. Then the mesopause temperature (\bar{T}_{msp}) and height (\bar{z}_{msp}) are calculated from \bar{T}_{bcrt}^{year} .
469 Such that the trends of the mean temperature and the mesopause structure can be studied in each YC
470 at high latitudes using MLR. The main results are summarized as below:

471 The cooling trends are significant in the MLT region and coincide well with previous results at
472 50°S – 50°N . At latitudes higher than 55°N , the new findings are that the cooling trends have
473 magnitudes of ≥ 2 K/decade at northern high latitudes in February, April, and June and at southern
474 high latitudes in August, October, and December. There are also extreme cooling trends of ≥ 6
475 K/decade in the lower thermosphere at the northern highest latitude in February and June and at the
476 southern highest latitudes in August and December. Both the cooling and extreme cooling trends are
477 hemispheric and seasonal symmetric.

478 Besides the general cooling trends, there are also warming trends of 1 – 2.5 K/decade at 10^2 – 10^3
479 hPa and at latitudes higher than 55°N in October and December and at latitudes higher than 55°S
480 in April and August. The peaks of the warming trends vary from 4×10^{-3} hPa to 10^{-3} hPa in different
481 months. The warming trend in December coincides with previous observational and simulation

482 results.

483 The mean $\bar{T}_{msp}(z_{msp})$ in the northern summer polar region is colder (lower) than that in the
484 southern counterpart by a value of $\sim 5\text{--}11$ K (~ 1 km) over the past 22 years. Although the trends of
485 \bar{T}_{msp} are highly dependent on latitudes and months, they are negative at most latitudes and have
486 larger magnitudes at higher latitudes. The trends of \bar{T}_{msp} at the southern high latitudes in December
487 are highly dependent on the data length. The trends of \bar{T}_{msp} change from warming of $0\text{--}2$ K/decade
488 during 2002–2023 to cooling of $1\text{--}2$ K/decade during 2002–2019. The significant dependence of the
489 trends of \bar{T}_{msp} on the data length might be caused by the large annual variability of z_{msp} at the
490 southern high latitudes in December.

491 The trends of the mean temperature in the MLT region and mesopause are revealed from
492 continuous observations of the SABER instrument over the past 22 years. The data length is long
493 enough to determine reliable trends. Our results provide an observational proof that the extreme
494 cooling trends at high latitudes are more sensitive to the changing dynamics associated with climate
495 change and should be paid more attentions in future observational and model studies.

496 **Author contributions**

497 XL analyzed the data and prepared the paper with assistance from all co-authors. JX and JY
498 design the study. All authors reviewed and commented on the paper.

499 **Data Availability Statement**

500 All SABER data can be accessed from Space Physics Data Facility, Goddard Space Flight
501 Center (<https://spdf.gsfc.nasa.gov/pub/data/timed/saber/> (last access: January 2024; Mlynczak et al.,
502 2023). The $F_{10.7}$ data were obtained from <https://spdf.gsfc.nasa.gov/pub/data/omni/> (last access:
503 January 2024; Tapping, 2013). The QBO data were obtained from https://acd-ext.gsfc.nasa.gov/Data_services/met/qbo/ (last access: January 2024; Baldwin et al., 2001). The
504 ENSO data were obtained from <https://www.psl.noaa.gov/enso/mei/> (last access: January 2024;
505 Zhang et al., 2019; Wolter and Timlin, 2011)

507 **Competing interests**

508 The authors declare that they have no conflict of interest.

509 **Acknowledgments**

510 This work was supported by the National Natural Science Foundation of China (41874182,
511 42174196), the Project of Stable Support for Youth Team in Basic Research Field, CAS (YSBR-
512 018), the Informatization Plan of Chinese Academy of Sciences (CAS-WX2021PY-0101), and the
513 Open Research Project of Large Research Infrastructures of CAS "Study on the interaction between

514 low/mid-latitude atmosphere and ionosphere based on the Chinese Meridian Project". This work
515 was also supported in part by the Specialized Research Fund and the Open Research Program of the
516 State Key Laboratory of Space Weather.
