## Abstract

Information on soil water potential is essential to assess soil moisture state, to prevent soil compaction in weak soils, and to optimize crop management. In lack of direct measurements, the soil water potential values must be deduced from soil water content dynamics that can be monitored at plot scale or obtained at larger scale from remote sensing information. Because the relationship between water content and soil water potential in natural field soils is highly ambiguous, the prediction of soil water potential from water content data is a big challenge. The hysteretic relationship observed in nine soil profiles in the region of Solothurn (Switzerland) is not a simple function of texture or wetting and drainage cycles but depends on seasonal patterns that may be related to soil structural dynamics. Because the physical mechanisms governing seasonal hysteresis are unclear, we developed a deep neural network model that predicts water potential changes using rainfall, potential evapotranspiration, and water content time series as inputs. To adapt the model for multiple locations, we incorporated a Deep Autoencoder Neural Network as a classifier. The autoencoder compresses the water content time series into a site-specific feature that is highly representative of the underlying water content dynamics of each site and quantifies the similarity of dynamic patterns. By adding the Autoencoder's output as an additional input and training the neural network model with three stations located in three major classes founded by the autoencoder, we predict matric potential for other sites. This method has the potential to deduce the dynamics of matric potential from water content data (including satellite data) despite strong seasonal effects that cannot be captured by standard methods.

## 1. Introduction

The soil water characteristics curve SWC relates the matric potential (MP) and water content (WC) and is the key physical property to quantify soil water dynamics [\(Tuller & Or, 2023\)](#),[\(Tuller and Or, 2023\)](#).

The SWC (also denoted as soil water retention curve or pressure-saturation relationship) depends on both soil texture and structure and differs with soil types and soil textural classes [\(Rawls, et al., 2003; Shwetha & Varija, 2015\)](#), [\(Rawls et al., 2003; Shwetha and Varija, 2015\)](#). The SWC contains information on the pore size distribution and allows the assessment of flow and transport properties for different hydration states [\(Rostami, et al., 2015; Menon, et al., 2020\)](#),[\(Menon et al., 2020; Rostami et al., 2015\)](#). To provide a complete characterization of the actual soil moisture state and flow regimes, information on both the matric potential and the water content must be specified. Information on volumetric water content is needed to assess the free storage capacity, optimize water management, and to formulate mass balance. The matric water potential is a component of the total and hydraulic soil water potential and determines the water flow in direction of decreasing water potential to achieve equilibrium with its surroundings [\(Ma, et al., 2022\)](#),[\(Ma et al., 2022\)](#). The matric potential is also of particular interest to assess mechanical stability of a soil [\(Holthusen, et al., 2010; Lu, et al., 2010\)](#) [\(Holthusen et al., 2010; Lu et al., 2010\)](#). The capillary and adsorptive forces expressed with the matric potential define the unsaturated soil strength mitigating soil compaction by heavy machinery in construction work, farming, and forestry [\(Smith, et al., 2001\)](#),[\(Smith et al., 2001\)](#). For example, matric potential thresholds are defined in various regions of Switzerland to prevent mechanical damage and regulate the maximum load linked to factors like soil type, texture, and vehicle impact (Bundesamt für Energiewirtschaft, 1997). Other important potential thresholds are the wilting point and the field capacity, characterizing the plant available water [\(Gupta, et al., 2023\)](#),[\(Gupta et al., 2023\)](#).

It would be optimal to determine the soil moisture status relative to these potential thresholds based on information of water content using the SWC, without direct measurement of the matric potential. In that case, matric potential dynamics could be deduced from remote sensing water content data that are available at various scales. However, the application of this procedure is limited by two effects. Firstly, under saturated conditions, the water potential can change without modifying the volumetric water

61 content. The transition of conditions with negative water potential within the capillary fringe to positive  
62 pressures below a water table is crucial for the triggering of landslides (~~Gallipoli, et al., 2003~~)([Gallipoli  
63 et al., 2003](#)). Secondly, the SWC under field conditions is often an ambiguous relationship between  
64 potential and water content due to hysteretic and dynamic effect as will be discussed next.

65 The SWC is typically measured in the lab as series of equilibrium states obtained during drainage, with  
66 one water content value assigned to the applied pressure. The results of such small-scale experiments  
67 are not sensitive to structural pores that can be found at the field scale (~~Romero Ruiz, et al.,  
68 2018~~)([Romero-Ruiz et al., 2018](#)) and can thus be expressed as function of basic soil properties (texture,  
69 bulk density, content of organic material) using pedotransfer functions (PTF; ~~Zuo &and~~ He, 2021).  
70 Because these PTFs ignore the effects of soil structures including macropores and cracks (~~Basile, et al.,  
71 2019~~)([Basile et al., 2019](#)) and are trained with data from small samples with artificially high initial  
72 saturation conditions, their applicability to model dynamic processes in the field is limited. Another  
73 limitation is the underlying assumption of an unambiguous relationship between water content and  
74 matric potential (and hydraulic conductivity). In all land surface models, water content is linked by an  
75 unambiguous relationship between water content and matric potential. In reality, this relationship is  
76 highly ambiguous under field conditions as was analyzed in detail by ~~Hannes et al. (2016)~~([2016](#)) and  
77 as we will show later in this paper as well.

78 ~~Hannes et al. (2016)~~([2016](#)) analyzed long-term experiments and concluded that the high variation of  
79 matric potential values for the same water content are a result of hysteresis, dynamic effects, and  
80 structural changes during the season. Hysteresis is related to differences in wetting and drying cycles  
81 (~~Capparelli & Spolverino, 2020~~)([Capparelli and Spolverino, 2020](#)) as controlled by different pore  
82 structures controlling air- or water invasion and differences in receding or advancing wetting angles  
83 (~~Fomin, et al., 2023~~)([Fomin et al., 2023](#)). Hysteresis is often manifested in coarse textured soils and  
84 occurs as well during slow processes. Another process resulting in an ambiguous pressure-saturation  
85 relationship is dynamic effects with water contents that are not in equilibrium with the quickly changing  
86 potential (~~Ross & Smettem, 2000~~)([Ross and Smettem, 2000](#)). Finally, the size of structural pores is  
87 not constant with time but changes with season, water content, and soil formation processes (~~Fu, et al.,~~

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

88 ~~2021~~. (Fu et al., 2021). The combined effect of hysteresis, non-equilibrium, and structural changes  
89 makes it extremely challenging to deduce soil matric potential from information on water content. Also,  
90 the implementation of these combined effects in physically-based models of unsaturated water flow is  
91 not straightforward. As an alternative approach to physically-based models, machine learning can be  
92 applied to simulate the complex relationship between matric potential and water content under field  
93 conditions. In this study, we will apply a deep neural network (DNN).

94 Deep neural networks (DNN) have demonstrated their effectiveness as a powerful numerical tool for  
95 resolving complex patterns. Their ability to learn from data and recognize intricate relationships makes  
96 them valuable in various fields, including the modeling of soil water characteristics. For example, Jain,  
97 et al. (2004)(2004), and Achieng (2019)(2019) used artificial neural network (ANN) models to predict  
98 the hysteretic water content from observed matric potential values. However, both publications  
99 simulated lab data under equilibrium conditions and cannot be applied for the more complex dynamic  
100 processes in the field. In addition, the models were site-specific and needed both water content and  
101 matric potential information for the training. Here we will apply a different DNN using an autoencoder  
102 approach. As we will explain in the theory section, the autoencoder condenses the complexity of  
103 temporal (and spatial) patterns into a single (or a few) number(s). The hypothesis of this study is that  
104 the autoencoder value is a new and unique characterization of the soil moisture dynamics and can be  
105 used to predict matric potential dynamics from observed water content data. The paper is organized as  
106 follows: in section 2, the study sites and the basics of the deep neural network with the autoencoder  
107 approach are presented. The results section compares the model performance of site-specific deep  
108 neural network (DNN) and shows the possibility to build a generalized DNN using the autoencoder  
109 analysis as model input. Limits and possible applications of the model approach are discussed in section  
110 5.

## 111 2. Material and methods

112 In a first step, matric potential time series were simulated at nine sites in the region of Solothurn  
113 (Switzerland) using site specific ANN model, to proof that the ANN models can predict matric potential

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

114 from water content dynamics with site specific training. In the next step, the autoencoder analysis of  
115 water content dynamics of all sites was conducted. Finally, the site-specific ANN model was enhanced  
116 and transformed into a multisite model by combining two deep neural networks. This transformation  
117 allowed for a more comprehensive and versatile predictive framework of matric potential as function  
118 of water content.

## 119 2.1 Study area and soil moisture data

120 The study area covers mainly the canton of Solothurn in Switzerland (Fig.1), and thus an area of  
121 approximately 629 km<sup>2</sup>. The climate in Solothurn is classified as oceanic climate (Cfb) according to  
122 Koppen and Geiger climate classification, with an average yearly temperature of 9.5 °C and annual  
123 precipitation of around 1400 mm. Approximately half of the annual precipitation in the canton  
124 undergoes the process of evaporation (Spreafi ~~and~~ Weingartner, 2005). During the year, the average  
125 temperature varies by 19 °C with the highest temperature occurring in the month of July and the lowest  
126 average temperature in January. Regarding precipitation patterns, the month of June has the highest  
127 level of precipitation, while March stands out as the driest month. Soil moisture dynamics (see below)  
128 were studied for the period from 2011 to 2022. For this period, climatic data was available on the data  
129 portal of MeteoSwiss (~~IDAweb~~(IDAWEB, 2024) . The data was gathered from the closest  
130 meteorological stations to each of the nine sites in the Solothurn region.

131 Soil moisture data were downloaded from the ‘soil monitoring network’ (BODENMESSNETZ, 2024)  
132 collecting data from 65 stations distributed over eleven cantons of Switzerland. The network’s primary  
133 objective is to provide real-time soil moisture information for mitigating soil compaction.  
134 BODENMESSNETZ also plays a role in raising awareness among farmers and foresters about soil  
135 compaction, providing a tool to assess the current situation and adjust the use of heavy machinery based  
136 on weather conditions. As the network has been running since 2011, it now serves as a valuable resource  
137 by offering long-term diverse information, including land use, precipitation amounts, and matric  
138 potential measured at various depths (20 and 35 cm depth in most of the stations, using T8 and T32  
139 tensiometers from METER group). Only at nine sites that are located in the region of Solothurn, the  
140 water content was measured at 20 cm depth (Stevens Hydra Probe). For these nine sites, daily values in

Formatted: Font color: Black

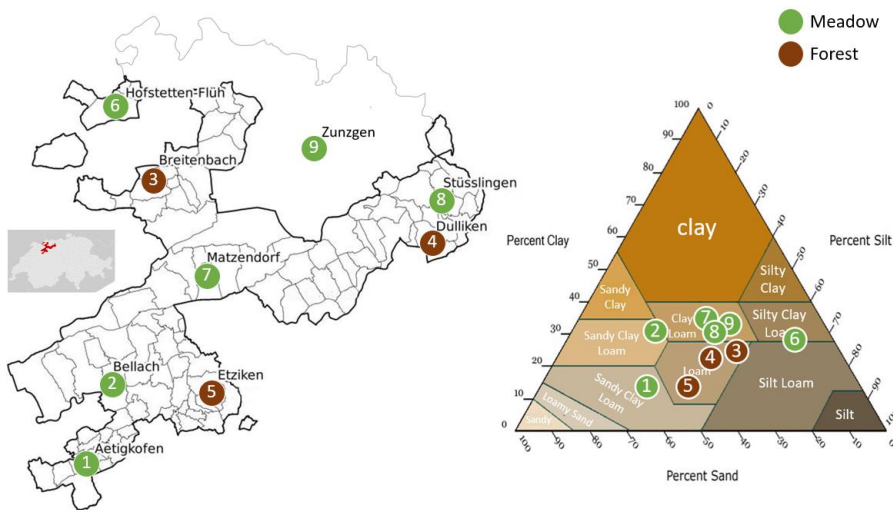

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

141 volumetric water content (20 cm), matric potential (20 cm) and precipitation values were used. The  
 142 matric potential in the downloaded data was given in kPa and was transferred to matric potential head  
 143 with units of cm (1 cm is 0.1 kPa), considering a water density of  $1000 \text{ kg m}^{-3}$  and gravity acceleration  
 144 of  $10 \text{ m s}^{-2}$ .

145 As the soil moisture decreases, water is drawn from the tensiometer, creating a negative pressure or  
 146 tension. During dry periods, cavitation may occur, causing water vaporization and air bubble formation  
 147 (Mendes & Buzzi, 2013) (Mendes and Buzzi, 2013), or tensiometers had to be refilled (Sadeghi, et al.,  
 148 2020) (Sadeghi et al., 2018). To address these challenges and ensure accurate data collection, various  
 149 data preprocessing and filtering techniques were implemented. These techniques involved identifying  
 150 and removing outliers, systematically excluding data points with water potential values within the  
 151 problematic dry ranges and filtering out data points with extremely low or high water content values.  
 152 The study also flagged abrupt changes in volumetric water content (VWC) and matric potential (MP)  
 153 for further investigation, as these could indicate measurement anomalies. Additionally, a thorough  
 154 analysis of weekly trends in the data was conducted to identify systematic variations over time (see  
 155 Appendix A).

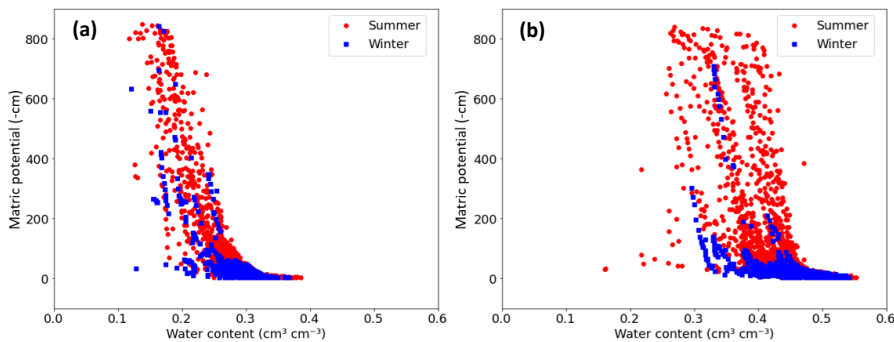

156  
 157 **Figure 1** Overview of the study area with site locations, soil texture, and land cover. The primary focus  
 158 is on the canton of Solothurn, outlined by the black border on the map, with an additional site from the

159 canton of Basel (site 9, Zunzgen). Within this region, three sites are categorized as forests, while the  
160 remaining six sites are designated as meadows. The analyzed soil horizons (20 cm depth) of the study  
161 area encompasses five soil textural classes as shown in the soil texture triangle.

162 The analyzed soil horizons of the selected locations can be assigned to five different soil textural classes  
163 (figure 1) and two different land covers (meadow and forest). The location denoted as Matzendorf (site  
164 #7) contains the highest clay content, whereas locations such as Aetigkofen (site #1) are predominantly  
165 sandy. Across these nine locations, different relationships between matric potential and water content  
166 were deduced from field data as shown in Figure 2 for two sites with low and high variations in water  
167 content for similar potential values. To show the relevance of seasonal patterns, we differentiate  
168 between summer (April to September) and winter period (remaining months).

169

170

171 **Figure 2** Soil-Water characteristics curve (SWC) measured in the field at two sites classified into  
172 summer (April to September) and winter period (remaining months) from 2012 to 2023. (a) The Etziken  
173 site (site #5) shows small changes in the SWC dynamics over the years, for both the warm and cold  
174 period. (b) A contrasting scenario was found for the site in Bellach (site #2) that was characterized by  
175 a wide range of water content for similar potential values. The unit of matric potential, represented as -  
176 cm, is equivalent to -0.1 kPa.

## 177 2.2 Deep neural network (DNN)

178 A basic artificial neural network (ANN) comprises one or two hidden interconnected layers, with each  
179 layer tasked with the conversion of an input vector ( $\mathbf{x}$ ) into a hidden state vector ( $\mathbf{h}$ ), as described by  
180 [\(Bertels & Willems, 2023\)](#); [\(Bertels and Willems, 2023\)](#). This conversion is accomplished with eq. (1):

$$181 \mathbf{h} = f(\mathbf{x}) = \text{act}(\mathbf{W} \cdot \mathbf{x} + \mathbf{b}) \quad (1)$$

182 Where  $f(\mathbf{x})$  represents the transformation function applied to the input vector ( $\mathbf{x}$ ), with a weight matrix  
183 ( $\mathbf{W}$ ) and a bias vector ( $\mathbf{b}$ ), integrated with an activation function (denoted as " $act$ ").

184 To construct a deep neural network (DNN), multiple layers (more than two hidden layers) are  
185 interconnected to form a 'multilayer perceptron.' The training process involves finding optimal values  
186 for the weights and biases in the network using suitable optimization techniques ~~(Bertels & Willems,  
187 2023)~~. [\(Bertels and Willems, 2023\)](#). In this study, DNN was built to predict the daily MP for the nine  
188 sites. The process involved several key steps. First, in the design of the neural network, activation  
189 functions were carefully selected and integrated to introduce non-linearity into the model's  
190 transformations ~~(Montesinos López, et al., 2022)~~. [\(Montesinos López et al., 2022\)](#). The Rectified  
191 Linear Unit (ReLU) activation function was employed to mitigate vanishing gradient problem and  
192 enhance the model's ability to handle noisy input. The inclusion of ReLU was motivated by  
193 considerations of computational efficiency, with some attention given to the potential issue of "dying  
194 ReLU" ~~(Montesinos López, et al., 2022; Lu, 2020)~~. [\(Lu, 2020; Montesinos López et al., 2022\)](#).

195 Next, the neural network was structured with a total of six layers, including four hidden layers as  
196 suggested by ~~Achieng (2019)~~[\(2019\)](#). All layers were densely connected, fostering strong information  
197 flow between neurons. Crucially, batch normalization was incorporated after the second hidden layer.  
198 Batch normalization is a technique that normalizes the activations within a layer during training, which  
199 can help mitigate issues like internal covariate shift and accelerate convergence ~~(Ioffe, 2015)~~. [\(Ioffe and  
200 Szegedy, 2015\)](#). The choice of the optimization method was the Adam optimizer, a powerful tool for  
201 training neural networks. It adaptively adjusted learning rates, thereby optimizing the learning process,  
202 and enabling rapid convergence while employing Mean Squared Error (MSE) as the loss function  
203 ~~(Kingma & Ba, 2014)~~. [\(Kingma and Ba, 2014\)](#). To prevent overfitting by the Adam optimizer, an early  
204 stopping mechanism was implemented. This mechanism continuously monitored the loss function for  
205 the hold out data during training, ceasing the process if no improvement or a sudden increase was  
206 detected over a predetermined number of consecutive epochs.

207 The initial deep neural networks (DNN) were configured with 4 input parameters and the daily  
208 logarithmic scaled matrix potential (MP) value as output. The input parameters consisted of

Formatted: Font color: Black

209 precipitation, potential evapotranspiration, measured VWC, and the weekly percentage change in  
210 VWC. As the prediction process progressed, two major issues were identified. Firstly, the influence of  
211 the VWC measurements on the training process was found to be predominant. Consequently, a decision  
212 was made to increase the weight of precipitation and potential evapotranspiration in the calculation  
213 process by incorporating three new input parameters: the weekly total precipitation and  
214 evapotranspiration (the sum of the current day and the preceding six days), along with the difference  
215 between these two new components. Secondly, the use of logarithmic scaled MP values was found to  
216 be highly sensitive to data availability. Therefore, a decision was made to retrain the model using  
217 absolute linear MP values (see Appendix B). In total, the final model was equipped with 7 input  
218 parameters to predict the absolute linear MP values for a given location. For each site, a site-specific  
219 DNN was built. The extent of the training data is predominantly influenced by site-specific  
220 characteristics. For instance, sites characterized by sandy soils necessitated a shorter training duration  
221 in contrast to sites with a higher clay content. Typically, the training dataset spanned a duration of 4 to  
222 7 years. During this period, 70% of the data were randomly selected for training, while the remaining  
223 30% were set aside as holdout data ~~(Gholamy, et al., 2018).~~ [\(Gholamy et al., 2018\)](#). The extra years of  
224 data beyond the initial training period were reserved for validation purposes.

### 225 2.3 Autoencoder neural network

226 The autoencoder, consisting of an encoder and a decoder, is an unsupervised deep neural network that  
227 learns how to efficiently compress input data into a meaningful representation and subsequently  
228 reconstruct the original data from this compressed form ~~(Chen & Guo, 2023).~~ [\(Chen and Guo, 2023\)](#).  
229 By connecting the encoder and decoder, the autoencoder effectively captures important patterns and  
230 variations present in the data, enabling comprehensive analysis and interpretation ~~(Chen & Guo, 2023).~~  
231 [\(Chen and Guo, 2023\)](#). In this study, an autoencoder neural network (figure 3) was built to analyze the  
232 measured VWC time series at 20 cm depth for the 9 sites.

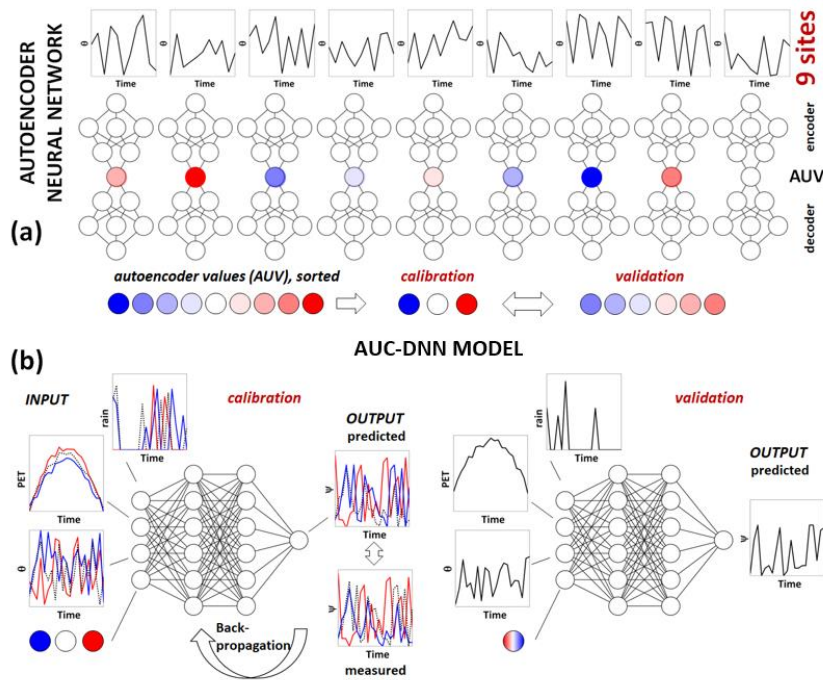

233

234 **Figure 3** Autoencoder deep neural network for volumetric water content dynamic analysis. In this  
 235 illustration, a densely connected autoencoder is utilized to compress the dynamic information of  
 236 Volumetric Water Content (VWC) into a singular value, AUV, highlighted in red. The process begins  
 237 with the encoder, depicted in blue, extracting the AUV from the measured volumetric water content  
 238 time series (left orange layer). Subsequently, the densely connected decoder, represented in green,  
 239 utilizes the AUV to reconstruct the VWC (orange layer at the right). Both the encoder and decoder,  
 240 characterized by dense connections, optimized the AUV value by minimizing the error between the  
 241 measured VWC and the reconstructed VWC.

242 The process was as follows. Firstly, an encoder neural network was created for each site. Its objective  
 243 was to take the VWC time series as input and gradually reduce its dimensionality through hidden layers  
 244 ~~(Chen & Guo, 2023)~~. ~~(Chen and Guo, 2023)~~. The encoders' output was a single site-specific latent  
 245 representation, called Autoencoder Value (AUV), and captures essential features of the VWC dynamics  
 246 ~~(Chen & Guo, 2023)~~. ~~(Chen and Guo, 2023)~~. Subsequently, a decoder neural network was developed  
 247 to utilize the AUV value as reference to reconstruct the original VWC time series data. The success of  
 248 this reconstruction depends on the training process, which aimed to optimize the AUV value by  
 249 minimizing the error between the original VWC time series and its reconstructed counterpart by  
 250 minimizing the mean squared error (MSE) value to less than 0.1.

251 After the optimization process, for each site one autoencoder value (AUV) was obtained. These AUV  
 252 were scaled and then used to build a combined model (Figure 4) as follows. The AUV were sorted into  
 253 three categories. Subsequently, one site from each category was selected. Finally, the data from the  
 254 three chosen sites, each representing one category, were used to train the combined AUC-DNN model.  
 255 The final combined model was thus equipped with 8 input parameters to predict the dynamic MP for a  
 256 specific location. These parameters consisted of the same 7 inputs employed in the DNN model (section

257 2.2), complemented by the AUV. The neural network structure, as detailed in section 2.2, remained  
 258 unchanged, employing the same optimization techniques.

259  
 260 **Figure 4** Application of two different types of deep neural network for the prediction of matric potential  
 261  $\psi$ . In this conceptual example, the water moisture dynamics of nine sites is considered. (a) The  
 262 autoencoder neural network captures the characteristic features of the soil water content ( $\theta$ ) dynamics,  
 263 assigning an autoencoder value (AUV) to each site. These values are sorted to AUV classes (one site  
 264 from each class was used for calibration, remaining sites for validation). (b) The combined AUC-DNN  
 265 model is built using the calibration sites with rainfall, potential evapotranspiration (PET), water content,  
 266 and AUV as part of the 8-input parameters. The predicted matric potential ( $\psi$ ) is compared to measured  
 267 values for backpropagation. The calibrated DNN is then used to predict  $\psi$  for the remaining sites.

268 Initially, 70% of the data from each of the training sites were randomly selected for the training dataset.  
 269 Subsequently, the remaining 30% of the data were set aside as the holdout dataset, serving as a  
 270 benchmark for assessing model performance. The developed AUC-DNN was then applied for the other  
 271 six sites (with the same input variables including AUV) to predict the entire datasets of those unseen  
 272 sites. The combined model has thus the strengths of both components—the DNN' ability to understand  
 273 dynamic MP patterns and the feature extraction capabilities of the autoencoder. This shift in the model's

274 strength extends it from being site-specific to encompassing multiple sites, enabling it to gain a broader  
275 understanding of how the dynamic MP and AUV values relate.

## 276 2.4 Statistical evaluation

277 The evaluation of model performance is carried out by comparing the model predictions to the measured  
278 data. While there is no universal consensus on a standardized evaluation procedure, it is widely  
279 recognized that a multi-objective approach should be adopted e.g., ~~(Boyle, et al., 2000; Willems, 2009);~~  
280 ~~(Boyle et al., 2000; Willems, 2009)~~. In this study, a combination of four evaluations tools was adopted.  
281 First, a scatter plot of observations against simulated values was utilized to visualize the degree of  
282 alignment with the identity line (often referred to as the 1:1 line). This graphical approach allowed for  
283 a qualitative assessment of model performance. A closer concentration of data points near the 1:1 line  
284 indicated higher agreement between calculated and observed values. Moreover, this graphical method  
285 includes the 95 % confidence interval area which help in scrutinizing the model's consistency across  
286 different prediction ranges and detecting potential biases within the model's performance ~~(Ritter &~~  
287 ~~Muñoz-Carpena, 2013)~~ ~~(Ritter and Muñoz-Carpena, 2013)~~. The second criterion evaluates the  
288 distribution of (signed) prediction errors (eq(2)). Ideally, the error distribution should be centered  
289 around zero, following a normal distribution pattern around this point with low standard deviation. Such  
290 a distribution indicates an unbiased model with errors that tend to balance out. Deviations from this  
291 pattern may suggest model bias or other unexpected characteristics in the prediction errors ~~PE~~ ~~(den~~  
292 ~~Ouden, et al., 2012).~~

$$293 PE = O_i - P_i \quad (2)$$

294 with observed  $O_i$  and predicted matrix potential value  $P_i$ . The third evaluation metric was the root means  
295 squared error (RMSE; eq (3a)). RMSE with a value of zero indicates perfect fit, while higher RMSE  
296 value means worse model performance ~~(Ritter & Muñoz-Carpena, 2013)~~. ~~(Ritter and Muñoz-Carpena,~~  
297 ~~2013)~~. The final criterion for model evaluation involved the use of the dimensionless goodness-of-fit  
298 indicator (eq (3b)), known as the ~~(Nash & Sutcliffe, 1970)~~ coefficient of efficiency (NSE); ~~Nash and~~  
299 ~~Sutcliffe, 1970)~~. NSE, which ranges from negative infinity to 1, serves as an indicator of model  
300 performance, with a value of 1 indicating a perfect fit, while a negative NSE suggests that using the

Formatted: Font color: Black

Formatted: Font color: Black

301 means of the observed values is a better representative for the data than the evaluated model itself (Ritter  
302 & Muñoz-Carpena, 2013; Gupta & Kling, 2011). (Gupta and Kling, 2011; Ritter and Muñoz-Carpena,  
303 2013). A NSE value > 0.75 indicates a very good model, while an NSE value < 0.5 signifies  
304 unsatisfactory results (Moriassi et al., 2007). In Gupta et al. (1999) a threshold NSE-value of 0.80 was  
305 used for good model performance and is applied here as well. The RMSE and NSE are defined by:

$$306 \quad RMSE = \sqrt{\frac{\sum(O_i - P_i)^2}{N}} \quad (3a)$$

$$307 \quad NSE = 1 - \frac{\sum(O_i - P_i)^2}{\sum(O_i - \bar{o})^2} \quad (3b)$$

308 where  $O_i$  represents the measured value,  $P_i$  the simulation output, and  $\bar{o}$  the mean of the observed values,  
309 all within the context of a sample size  $N$ .

### 310 3. Results

311 Following the model discussion in section 2.2 and 2.3, we present first the results of the site-specific  
312 tests of predicting matric potential dynamics with a deep neural network (water content, rainfall and  
313 evapotranspiration as input data), before the role of autoencoder value is considered.

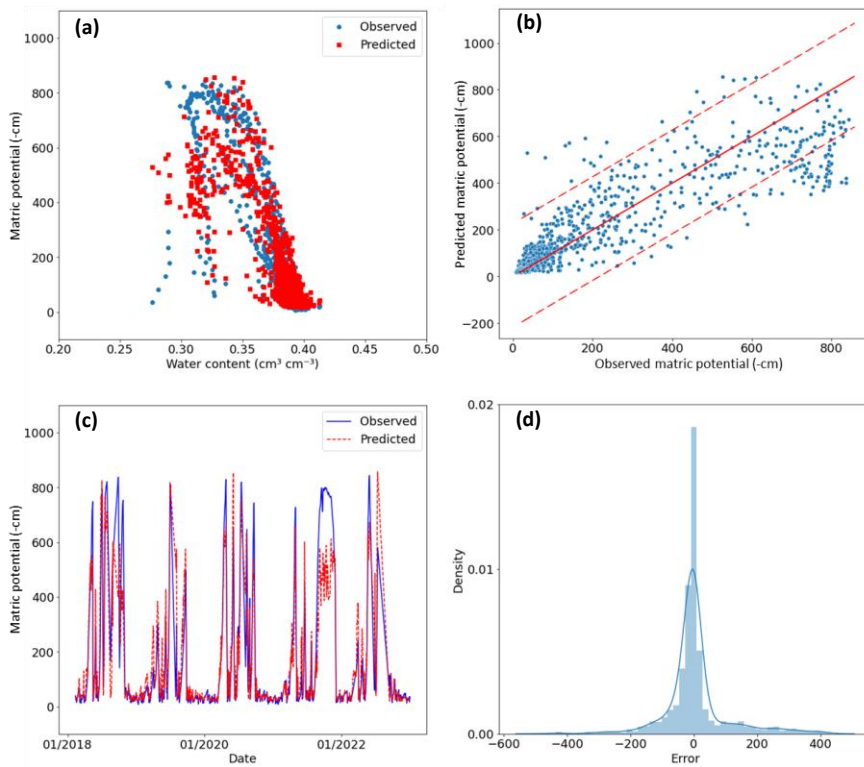

#### 314 3.1 Deep neural network modeling without autoencoder

315 The site-specific DNN model was used to simulate the time series for all nine sites. In Figure 5, the  
316 results are shown for the Stüsslingen site (size #8, clay loam, meadow). The model was trained on data  
317 that had 1825 days of observations from January 2012 to January 2020. The data was split randomly  
318 into two parts: 1) a calibration dataset that had 1277 days and 2) a holdout dataset that had 548 days.  
319 The model was then validated on data from February 2018 to January 2023 (1379 days). A strong  
320 agreement between the model and the observed data was discovered in both the training and validation  
321 datasets (figure 5c) as reflected by the low RMSE value and the high NSE value (table 1). Furthermore,  
322 it was noticed that the error distribution exhibited a predominantly normal pattern with minimal bias  
323 towards higher observed values compared to the predicted values (figure 5d). These findings suggest  
324 that the site-specific DNN-model was not only able to be generalized well to unseen data but also  
325 demonstrated a reliable ability to predict MP.

Formatted: Font color: Black

Formatted: Font color: Black

326 The statistical evaluation (Table 1) reveals a consistent performance across both the training and  
 327 validation periods for the Stüsslingen site, offering compelling evidence that the model avoids  
 328 overfitting. Additionally, when it comes to predicting MP values, the 95 % confidence interval indicates  
 329 that the model can capture well the overall dynamics (Figure 5b). However, the model performance  
 330 exhibits higher deviations for values exceeding 400 cm and consistently underestimates values higher  
 331 than 600 cm (figure 5b), which could explain the mild positive skewness observed in the distribution  
 332 of prediction errors in figure 5d.

333  
 334 **Figure 5** Graphical evaluation of the performance of the site-specific deep neural network (DNN) for  
 335 validation for the Stüsslingen site (site #8) for the validation period 2018 to 2022. **(a)** Comparison  
 336 between the simulated and measured soil water characteristics curve. **(b)** Scatter plot comparing  
 337 simulated and measured matric potential values, providing a visual representation of the level of  
 338 conformity to the identity line. The two dashed lines represent the 95% confidence interval around the  
 339 identity line, providing a visual assessment of the level of agreement. **(c)** Model validation presenting  
 340 time series with the observed and predicted matric potential. **(d)** Analysis of the distribution of  
 341 prediction errors (observed minus predicted values) with positively mild skewed distribution

342 Comparing the performance for the ‘holdout’ period (randomly chosen days between 2012 and 2019)  
343 of the nine site-specific DNN models, the NSE index is larger than 0.55 (‘good’) for all and larger than  
344 0.80 (‘optimal’) for six sites. For all sites it was thus possible to build a DNN model with good model  
345 performance for the randomly chosen test days. However, for the validation period, only four showed  
346 optimal performance (NSE > 0.80). For two forest sites with an optimal performance for the holdout  
347 period (Dulliken, site #4, and Etziken, site #5), the NSE dropped from a range between 0.82 and 0.88  
348 to a range between 0.73 and 0.75 (table 1). Obviously, the model captured the overall short term  
349 dynamics during training (randomly chosen days) but faced problems in the precise prediction of the  
350 long validation period. An extended training period may be necessary to enhance the model's accuracy  
351 for these specific sites. Three grassland sites (Bellach, site #2, Matzendorf, #6, and Hofstetten-Flüh, #5)  
352 showed good but not optimal performance already during the holdout period. As discussed in the next  
353 section, this may be related to large variations of the pressure values for similar water contents and the  
354 corresponding large AUV. Notably, the lower performance observed in the holdout period for  
355 Hofstetten-Flüh could be also linked to data limitations, as only 1200 days were used to train the model  
356 for this specific site (compared to 1825 sites for the other sites).

357 **Table 1** Statistical assessment of calibration (1825 days, until year 2019/2020) and validation results  
358 (years 2018/2019/2020 until years 2020/2021/2022) for nine sites. The holdout dataset was part of the  
359 training period and includes 548 days (30 % of calibration).

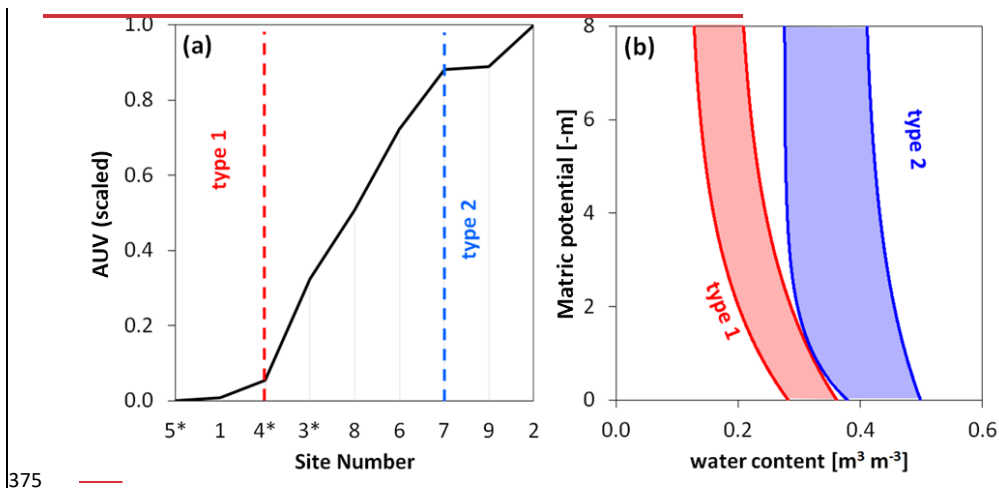

Location	AUV (-)	Training (holdout)		Validation	
		NSE (-)	RMSE (-cm)	NSE (-)	RMSE (-cm)
1 Aetigkofen	1.95	0.92	48	0.89	60
2 Bellach	7.00	0.70	98	0.62	125
3 Breitenbach <sup>a, b</sup>	3.56	0.86	82	0.83	96
4 Dulliken <sup>a</sup>	2.19	0.82	55	0.73	103
5 Etziken <sup>a</sup>	1.90	0.88	56	0.75	70
6 Hofstetten-Flüh <sup>b</sup>	5.59	0.76	90	0.63	123
7 Matzendorf	6.39	0.76	83	0.59	133
8 Stüsslingen	4.49	0.80	71	0.80	98
9 Zunzgen	6.44	0.87	62	0.83	73

360 <sup>a</sup> forest sites.

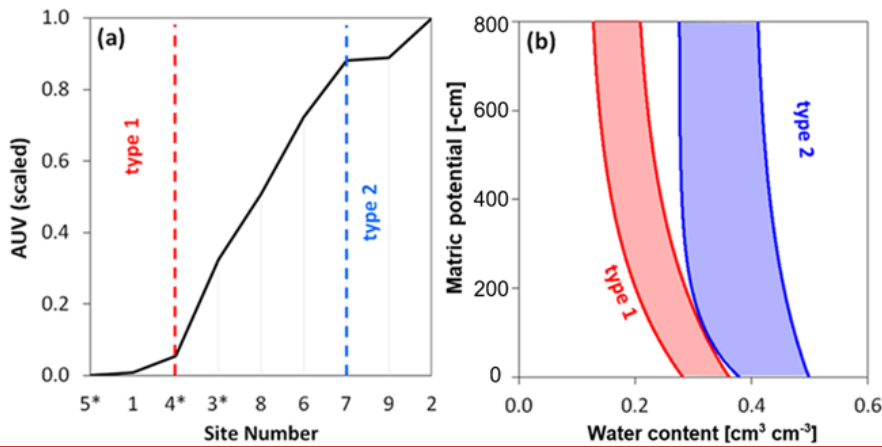

361 <sup>b</sup> Sites with limited available data. For those sites, only 1200 days were used for training; Within this training period, a subset  
362 of 360 randomly selected days was designated as a holdout dataset; the validation period for those specific sites was from  
363 2018/2019 to 2022.

364 3.2 Autoencoder DNN

365 The Autoencoder values (AUV) deduced from the time series analysis of the volumetric water content  
366 for the period 2012-2022 can be classified in three main groups (figure 6). Soil water characteristics  
367 curves (SWC) with low water content at saturated conditions and a small variation of water content for  
368 similar potential values are assigned to 'type 1', contrasting 'type 2' with large water content values  
369 and variations. These types of SWC are related to small ('type 1') and high ('type 2') autoencoder  
370 values (AUV). Sites with AUV between these two classes, are denoted in the following as 'transitional'  
371 type. As shown in Table 1, the AUV of forest soils are small (mainly 'type 1') with large NSE values.  
372 In contrast to the forest soils, there are grassland sites with high AUV ('type 2') but small NSE.  
373 Probably, the high variations of the SWC curve for 'type 2' require longer training periods to capture  
374 the high variations in the pressure-saturation relationship.

376  
 377 **Figure 6** Autoencoder value (AUV) and its relation to the soil water characteristics curve (SWC). **(a)**  
 378 The AUV of the nine sites with three sites of small (type 1) and three sites of high (type 2) AUV. **(b)**  
 379 The type 1 of the SWC has small water contents close to saturation and a narrower range of water  
 380 contents for similar water contents compared to type 2 with high water content values and variations.  
 381 Type 1 shows the data range of Aetigkofen (site #1) and Type 2 for Bellach site (#2). The site numbers  
 382 are chosen in alphabetic order and as shown in Figure 1 (Aetigkofen (1), Bellach (2), Breitenbach (3),  
 383 Dulliken (4), Etziken (5), Hofstetten-Flüh (6), Matzendorf (7), Stüsslingen (8), Zunzgen (9); sites with  
 384 forest are marked with \*).

### 385 3.3 Deep neural network using the autoencoder value (AUC-DNN)

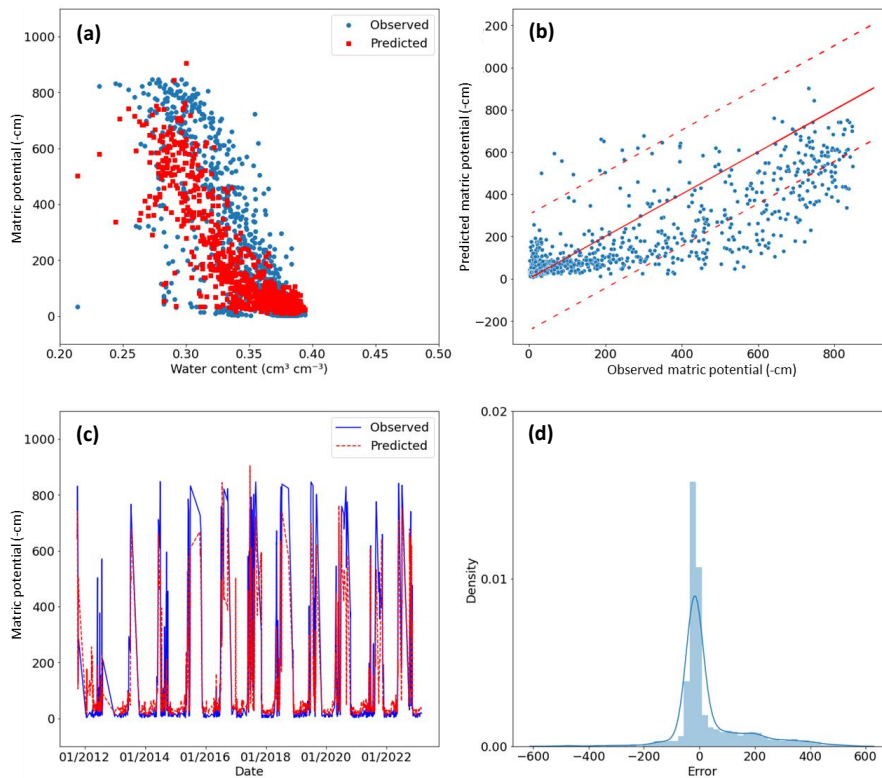

386 As mentioned in the previous section, the nine sites could be grouped into three main types according  
 387 to the scaled autoencoder value (AUV). Consequently, it was assumed that the creation of a DNN  
 388 model, which incorporates AUV in conjunction with the previously built site-specific neural network,  
 389 could enable predictions for unseen sites. Ideally, the model should be trained with a balanced dataset,  
 390 including one site from the 'type 1' category, one site from the 'type 2' category, and a few sites from  
 391 the 'transitional' category to capture the full transition between the 'type 1' and 'type 2'. However, due  
 392 to the data limitation, the model was trained for only three sites representing the three types (Etziken,  
 393 site #5, for 'type 1'; Bellach, #2, for 'type 2'; Stüsslingen, #8, for the 'transitional type') and was then  
 394 used to predict the six unseen sites. The impact of the small training set (only one site for transitional  
 395 type) was clear in the model results, which exhibited some instability, changing from one run to another  
 396 as the model was not able to assume the same transitional function between sites consistently. Therefore,  
 397 the model was run 20 times, then the average result for these runs was taken as a representative  
 398 outcome. The application of the new DNN model with AUV to predict the dynamic of matric potential

399 is shown in Figure 7 for Breitenbach (site #3, loam, forest) as unseen site. The model was found to fell  
 400 slightly behind the previously designed DNN model, but still can predict the dynamic in a good way.  
 401 Notably, the NSE value for this model for Breitenbach site was 0.71 over the entire period from 2012  
 402 to 2022 (Table 2).

403 **Table 2** AUC-DNN Model performance for the period 2012-2022. Three training sites were used to  
 404 build the AUC-DNN model that was then applied for the other six sites. The sites are listed according  
 405 to the corresponding autoencoder value (AUV). The asterisks mark the sites with forest; The AUV  
 406 was scaled from 1.9 to 7.0 to simplify input. Alternatively, scaled values ranging from 0 to 1 could  
 407 also be utilized.

Location	AUV	AUV (type)	used as	NSE (-)	RMSE
5 Etziken*	1.90	Type 1	Training site	0.82	70
1 Aetigkofen	1.95	Type 1	Validating site	0.76	88
4 Dulliken*	2.19	Type 1	Validating site	0.65	100
3 Breitenbach*	3.56	Transitional	Validating site	0.71	73
8 Stüsslingen	4.49	Transitional	Training site	0.85	116
6 Hofstetten-Flüh	5.59	Transitional	Validating site	0.60	113
7 Matzendorf	6.39	Type 2	Validating site	0.58	123
9 Zunzgen	6.44	Type 2	Validating site	0.69	104
2 Bellach	7.00	Type 2	Training site	0.71	104

408  
 409 It was noticed that the error distribution exhibited a predominantly normal pattern with a bias towards  
 410 higher observed values compared to the predicted values (figure 7d). The analysis indicates the model's  
 411 proficiency in forecasting dynamic trends rather than precise values (figure 7c). The results align with  
 412 the anticipated scenario as the AUV for Breitenbach (3.56) was relatively close the Stüsslingen AUV  
 413 value (4.49). Therefore, the underestimation detected in Stüsslingen for the site-specific DNN (figure  
 414 5b) is expected to exist in Breitenbach as well. The average model performance for all sites is presented  
 415 in Table 2. The NSE values was  $> 0.55$  for the 6 unseen sites (validating sites) and provided strong  
 416 evidence that the model can be relied upon for the dynamic MP predictions.

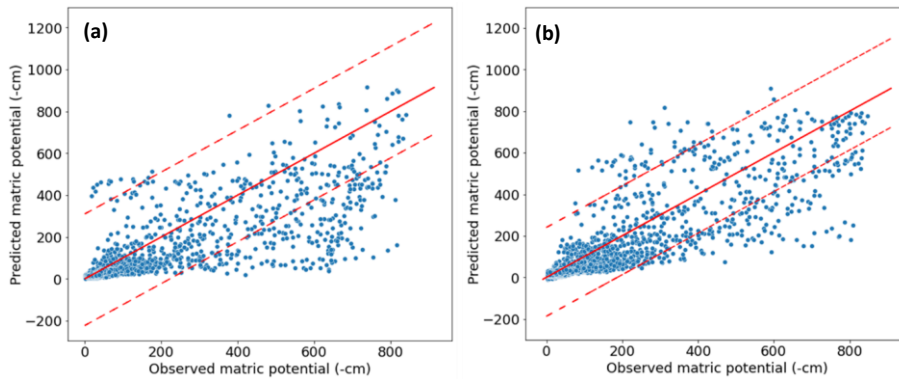

417

418 **Figure 7** Evaluation of the Deep Neural Network with Autoencoder (AUC-DNN) model performance  
 419 at the Breitenbach site for the period 2012-2022. **(a)** Comparison between the expected Soil Water  
 420 characteristics curve (SWC) and the observed SWC. **(b)** Scatter plot that compares observed data points  
 421 with their corresponding simulated values, providing a visual representation of the level of conformity  
 422 to the identity line. The two dashed lines represent the 95% confidence interval around the identity line,  
 423 providing a visual assessment of the level of agreement. **(c)** Time series comparison showing the  
 424 observed and predicted matric potential for the entire period. **(d)** Analysis of the distribution of  
 425 prediction errors (observed minus modelled value) using positively mild skewed distribution.

426 The NSE values for the unseen sites (validating sites) varied from 0.58 to 0.76, indicating a spectrum  
 427 of model performance, ranging from acceptable to good. The low NSE values observed for Matzendorf  
 428 (site #7) suggest that the model's utility is more suited for capturing overall trends and dynamics rather  
 429 than precise values. This evaluation was further supported by examining a scatter plot (Figure 8) that  
 430 compares the observed data points with their corresponding simulated values for the sites scored the  
 431 lowest and the highest NSE, Matzendorf (site #7) and Aetigkofen (site #1). The plot revealed a wider  
 432 95% confidence interval for Matzendorf (figure 8a) in comparison to Aetigkofen (figure 8b), indicating  
 433 that the lower the NSE value is, the more challenging it became for the model to predict the exact MP

434 values. However, the model performance indicated the ability of the AUC-DNN model to predict  
435 dynamic MP without the necessity of site-specific training data, marking a transition from the DNN  
436 site-specific nature to a more versatile multi-site model.

437  
438 **Figure 8** Comparison between observed data points and their corresponding simulated values for two  
439 sites with lowest and highest efficiency coefficient NSE. **(a)** Matzendorf (site #7) with NSE of 0.58. **(b)**  
440 Aetigkofen (site #1) with NSE of 0.76. The solid lines mark the 1:1 correspondence, the dashed lines  
441 the 95% confidence interval.

## 442 4. Discussion

443 Based on the analysis of the simulation results presented in section three, it can be asserted that the  
444 model was successfully built. However, as discussed in the next subsection, the model is expected to  
445 have certain drawbacks due to the limited number of available sites. In the other subsections, the  
446 relationship between the autoencoder value and soil properties and its application for satellite data will  
447 be discussed.

### 448 4.1 Limits of the deep neural network with autoencoder value (AUC-CNN)

449 First, the model's statistical evaluation revealed that the matric potential (MP) at a depth of 20 cm could  
450 be simulated with acceptable precision. However, a high variability in the evaluation is indicated by the  
451 NSE values for the unseen sites. This variance is attributed to the model's limited generalization  
452 capacity, as it was trained on just three sites. Furthermore, the model was not able to catch the whole  
453 dynamic for the training sites due to the limited length of available data. For example, Bellach (site #2),  
454 a training site that has a high AUV, had NSE value of 0.71 for the training period (table 2), which

455 indicates that the model was able to catch the general trend for this site, but still can't predict the exact  
 456 value of the MP. The effect of this result was obvious on the sites that are closed to AUV 'type two'  
 457 category (e.g., Hofstetten-Flüh and Matzendorf, sites #6 and #7, with NSE of 0.60 and 0.58,  
 458 respectively).

459 The stability of the AUC-DNN model was insufficient, as the model showed different prediction quality  
 460 upon running the model repeatedly for the same training sites (figure 9). This variability in the outcomes  
 461 indicates that the model can find different MP dynamics scenarios inside the training data. Therefore,  
 462 it is recommended to train the model for more than one site in the same AUV type.

463 **Figure 9** Variation of prediction results for 20 Runs for the AUC-DNN model quantified with the  
 464 efficiency coefficient NSE. The highest variation was with the unseen sites in the transitional and type  
 465 2 categories. Each box represents the interquartile range, with the line inside denoting the median. The  
 466 black diamond markers connect the mean values for each station, providing insight into the central  
 467 tendency of the data. Notches on the boxplots offer a visual indication of the uncertainty around the  
 468 median. The red dashed line represents the defined threshold for the NSE, set at 0.55 ; sites with forest  
 469 are marked with \*; training sites are highlighted in green.

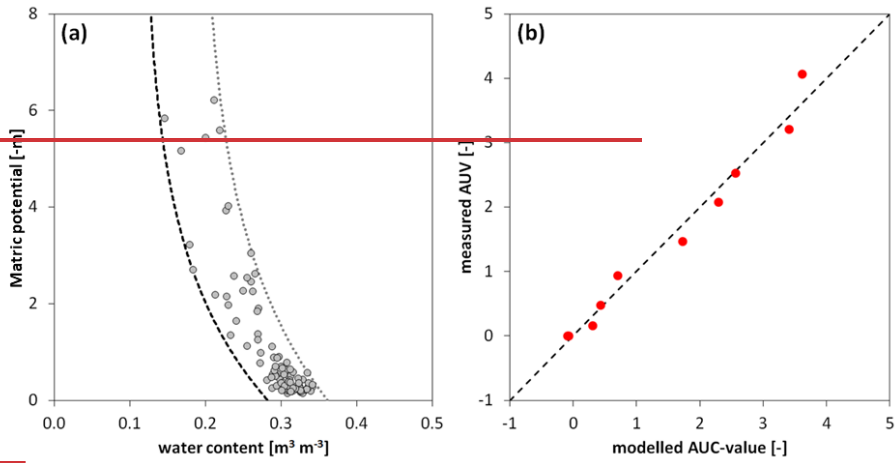

471 Especially for the 'transitional type', choosing a site in the beginning, in between, and in the end of the  
 472 category would stabilize the modeling results. However, in this study, there was no possibility to  
 473 provide the model with extra data to solve the prediction instability. Therefore, a solution was  
 474 implemented by 1) closely monitoring the model manually to ensure it captures the dynamic from all

475 three sites. This involved training the model with nearly identical time periods for each site and visually  
476 confirming comprehensive coverage of the cloud of points for the retention curve of each site, avoiding  
477 concentration on specific patterns during training. The process also includes 2) running the model for  
478 20 times, then averaging the results. Additionally, the statistical evaluation plots as shown in Figure 8,  
479 were used to detect instances with very low or very high MP prediction values.  
480 For the set of sites analysed in this study, the model showed good generalization capacity and stability.  
481 However, the nine sites were similar with respect to climate and geology and the range of soil textural  
482 classes (see Figure 1) was relatively narrow. In a future study, the AUC approach will be applied for  
483 sites differing in climate and soil textural classes. We expect that the model can predict the dynamic  
484 matric potential for a new site as long as the autoencoder value falls within the range of AUV of the  
485 training sites. To predict the soil moisture dynamics for soils with autoencoder values outside of the  
486 range of training data, the model must be re-built using additional training data.

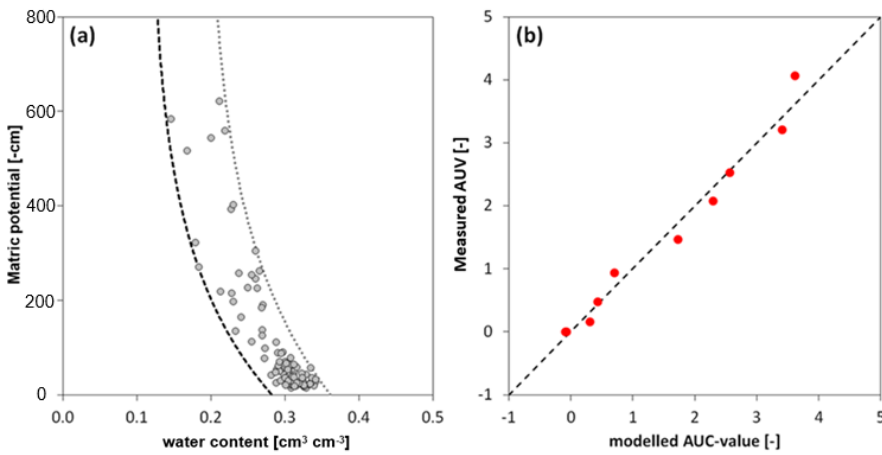

487

#### 488 4.2 Interpretation of AUV and its relationship to physical soil properties

489 As discussed in section 3.2, the autoencoder value (AUV) is low for soil water characteristics curves  
490 (SWC) with low saturated water content and low variations of water content for a certain matric  
491 potential value (type 1) and high AUV for large values and variations of water content (type 2). To  
492 provide a more quantitative relationship between SWC and AUV, the SWC data were characterized as  
493 follows: the time average of volumetric water content (VWC) and SWP were calculated for 15 days for  
494 the period 2015 to 2022. The envelope of these data was then calculated by fitting a minimum and  
495 maximum pressure saturation relationship including the averaged data (see Figure 10a).

496

497

498 **Figure 10** Relationship between autoencoder value (AUV) and soil water characteristics curve (SWC).  
 499 (a) 15-days average of SWC data for Aetigkofen (symbols; site #1). The two lines are exponential  
 500 functions building the envelope of the SWC curve. (b) Linear model for the nine sites linking the  
 501 parameters of the exponential model with the ‘measured’ AUV (deduced from measured water content  
 502 data).

503 The two boundary lines of the SWC were then characterized by a ‘saturated’ and ‘residual’ water  
 504 content and a shape parameter defining an exponential decrease of water content with increasing  
 505 absolute matric potential values. The SWC of each site can thus be described by six parameters (three  
 506 parameters per boundary line). As shown in Figure 10b, a linear model expressing the AUV as function

507 of these six parameters can be built. Simpler models with less parameters could not reproduce the AUV  
508 of all sites. Despite the positive correlation between AUV and average water content, the average water  
509 content alone is not sufficient to explain the range of AUV for all sites. Also combining average water  
510 content with soil texture information could not reproduce the AUVs of all sites, indicating that the soil  
511 moisture dynamics represented by AUV is not only dependent on static soil textural attributes but  
512 seasonal structural features as well.

513 Accordingly, there is no simple interpretation of AUV based on texture and average water content, but  
514 the dynamic variation of water content must be considered as well. Due to the relevance of the variation  
515 in water content for similar matric potential value, the use of a variational autoencoder (VAE) instead  
516 of the typical autoencoder could be considered. In contrast to the typical autoencoder that maps the  
517 input information into a single point (or a few points), the VAE produces a probability distribution  
518 capturing the variability (second moment) of the data. This could be specifically of interest for clay  
519 soils with high water contents (much larger than the residual water content) for the entire range of matric  
520 potential values. By including a probabilistic approach in the compressing and decompressing step, the  
521 variability of the data could be captured more efficiently using VAR.

522

#### 523 4.3 Application for satellite data

524 The AUC-DNN model was used to analyze satellite-based volumetric water content (VWC) satellite  
525 data, including SMAP L4 and L3, SMOS products, and Sentinel data. Subsequently, a comparison was  
526 carried out for the AUV for both site-specific measurements and earth observation (EO) measurements  
527 for the same region. The initial findings highlighted a disparity between the dynamics captured by EO  
528 products and the actual dynamics. Therefore, if the objective is to establish a robust system capable of  
529 detecting changes in water retention dynamics on a regional scale, it is considered necessary to enhance  
530 the calibration of EO in Europe. Only with EO-data that can reproduce the essential of the soil moisture  
531 dynamics as manifested in the AUV, the matric potential dynamics can be deduced from EO-data. For  
532 future EO-data with improved capacity to capture regional soil moisture dynamics, the concept

533 presented in this study (AUC-DNN) could be used to predict matric potential dynamics at global scale  
534 (see Appendix C).

## 535 5. Summary and conclusions

536 The soil water potential (SWP) determines water flow direction, water ability for plants, and mechanical  
537 stability. Because it cannot be measured directly by remote sensing techniques at larger scales, it is  
538 often deduced from water content information, assuming an unambiguous relationship between water  
539 content and SWP. However, this relationship under dynamic field conditions is highly ambiguous due  
540 to hysteresis, dynamic effects, and soil structural changes that cannot be modeled with a physically-  
541 based model. To enable prediction of SWP from soil water content, we apply a deep neural network  
542 (DNN) with an autoencoder to define unique features of the soil moisture dynamics. By inserting the  
543 autoencoder value (AUV) together with climatic data and water content measured at nine sites in the  
544 region of Solothurn (Switzerland) in a deep neural network (AUC-DNN), the soil water potential could  
545 be predicted. The main findings of the study can be summarized as follows:

- 546 • The SWC of the nine sites can be classified in three types based on the width of pressure-  
547 saturation relationship and the water content close to saturation
- 548 • These SWC-types are manifested in different autoencoder values (AUV)
- 549 • The AUV is not a simple function of average water content or soil texture but includes structural  
550 effects as well
- 551 • The AUC-DNN model could predict successfully the SWP dynamics of sites without site-  
552 specific training

553 The autoencoder value (AUV) is thus a new descriptor of the complex soil moisture dynamics that  
554 cannot be captured with physically based models. Future satellite generation may be sensitive enough  
555 to measure the AUV from remote sensing water content data. The approach presented in this paper will  
556 then enable the prediction of the soil matric potential at the global scale using remote sensing water  
557 content data.

## 558 Appendix A: Data Quality Assurance and Trend Analysis

559 As a precaution for data quality, the Absolute Matric Potential (AMP) and volumetric water content  
560 (VWC) data were scrutinized to identify potential errors the data. The process includes different steps  
561 that were necessary to discover anomalies, checking the integrity of the data, and detecting systematic  
562 changes with time.

### 563 **1- Flagging Abrupt Changes in VWC and MP:**

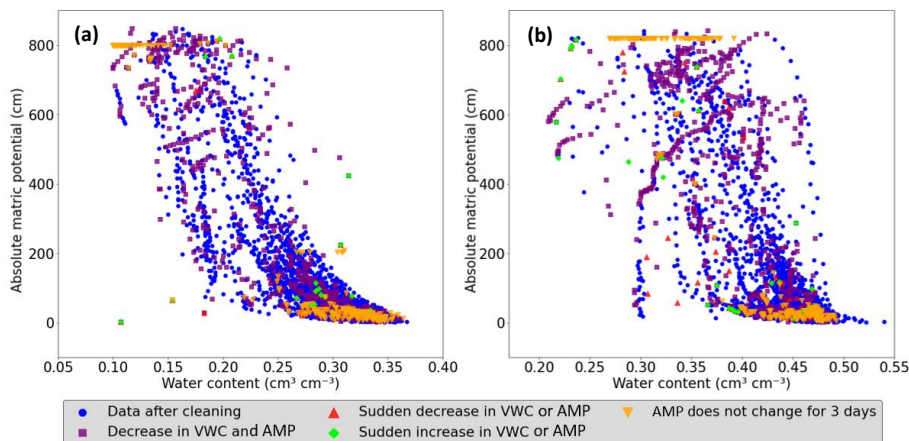

#### 564 **VWC Flagging and removing:** 565

- 566 • Differences between consecutive (daily) time steps in the water content time series were  
567 calculated.
- 568 • Instances with daily differences exceeding  $0.1 \text{ cm}^3/\text{cm}^3$  were flagged and denoted as sudden  
569 decreases or increases in VWC.
- 570 • Instances with VWC below  $0.1 \text{ cm}^3/\text{cm}^3$  or exceeding  $0.7 \text{ cm}^3/\text{cm}^3$  were identified and removed  
571 from the dataset. These extreme values were considered as measurement anomalies or outliers  
572 affecting the overall dataset's reliability.
- 573 • Instances with  $\text{AMP} < 1 \text{ cm}$  was removed from the data to overcome limitations in the used  
574 method. The water potential can change without modifying the volumetric water content after  
575 this limit, which could make the results of the model not accurate enough.
- 576 • The differences between consecutive time steps in AMP -time series was calculated; instances  
577 with daily differences exceeding 500 cm were flagged and called sudden decreases or increases  
578 in AMP (figure A1).
- 579 • The threshold AMP-value of 850 cm was employed in a specific step, where instances with  
580 AMP exceeding 850 cm were removed from the dataset, addressing the physical properties of  
581 water as it starts to boil in the tensiometers under pressure after this limit.
- 582 • Periods of concurrent decrease in AMP (indicator for wetting) and decrease in VWC (drying)  
583 were flagged (figure A1).

584 • Periods with matric potential values remaining constant over a three-day rolling window were  
585 flagged (figure A1).

## 586 2- Utilizing Index Windows for Data Manipulation and Data Removal

587 To address flagged instances mentioned before, a systematic approach is employed. For each  
588 flagged instance, three additional indices are generated around it to construct an index window,  
589 spanning one day before (index\_1), the flagged instance itself (index\_0), and two days after  
590 (index\_2 and index\_3). This four-day index window was eliminated from the dataset (figure  
591 A1). The decision to eliminate this window was informed by a visual assessment of  
592 measurements as it was noticed that when a measurement error occurs, the accuracy of the  
593 preceding day is affected. Furthermore, it was assumed that the device requires two subsequent  
594 days to restore normal measurement precision. This process contributes to a refined dataset,  
595 providing a more accurate representation of the underlying trends in AMP and VWC.

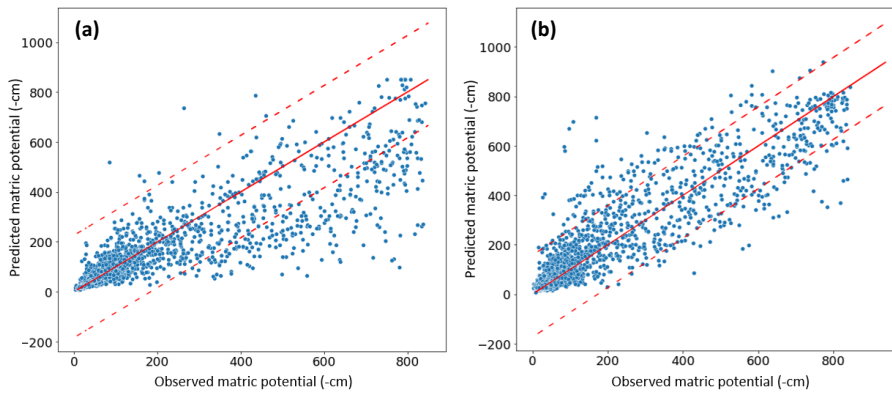

597 **Figure A1** Comparison of data before and after cleaning procedure: the blue circles depict the remaining  
598 data after applying the cleaning criteria. Each distinct marker represents eliminated points, each  
599 corresponding to a specific criterion (e.g., the square purple marker for simultaneous decrease in  
600 volumetric water content (VWC) and the absolute matric potential (AMP), the red upward-pointing  
601 triangle is the marker for sudden decreases, the lime diamond for sudden increases, and the orange  
602 downward-pointing triangle marks periods of unchanged AMP). This provides insights into the reasons  
603 for data removal and illustrates the profound impact of the data cleaning process in retaining high-  
604 quality data points. In (a) the cleaning process for sandy clay loam site in Aetigkofen (site #1) is shown,  
605 in (b) the cleaning process for the Matzendorf site (site #9, clay loam soil).

606 **Appendix B: Running the model with Logarithmic MP value.**

607 The AUC-DNN showed a good performance in predicting the dynamic MP for the different 6 unseen  
608 sites. However, it was clear that the model prioritizes tends to focus on capturing significant changes in  
609 values rather than accurately representing the values themselves. This tendency is attributed to the  
610 substantial difference between the highest and lowest absolute values (approximately 850 cm), leading  
611 the model to emphasize major fluctuations while neglecting minor ones. To address this issue and  
612 enhance the model's precision in capturing the exact AMP, a suggestion has been made to train the  
613 model for the same three sites but with the logarithmic value for the AMP. This modification aims to  
614 strike a better balance, ensuring that both major and minor changes are effectively captured while  
615 maintaining accuracy in representing the specific values of MP.

616 To qualitatively assess the model training performance under the logarithmic scale, a scatter plot (Figure  
617 B1) was generated, comparing observations against simulated values for the second training site  
618 (Stüsslingen). The reason for choosing a training site was to understand how the model captures the  
619 dynamics when trained with logarithmic matric potential. The results suggest that using logarithmic  
620 scale, the model prioritized the prediction of the exact absolute value of matric potential (AMP), which  
621 makes the model to optimize predictions for the absolute values between 0 to 200 cm. This approach is  
622 giving the same importance to small and large changes in the AMP, which causes that the model  
623 assigned a higher weight to small changes according to their higher frequency, while neglecting less  
624 frequently occurring major dynamic shifts. Consequently, the model's accuracy went down beyond 200  
625 cm (figure B1a) when compared to the model trained on non-logarithmic AMP-values (figure B1b). To  
626 maintain a balanced consideration of changes, logarithmic MP was avoided in the main part of the  
627 paper.

628

629 **Figure B1** Visual comparison of model performance, comparing the observed and simulated values for  
630 the Stüsslingen training site. **(a)** the model trained with logarithmically scaled AMP-values, while in  
631 **(b)** The model trained with absolute linear matrix potential (AMP) values. The solid line denotes the  
632 1:1 correspondence, and dashed lines represent the 95% confidence interval.  
633

## 634 Appendix C: SMAP data and Autoencoder for global scale analysis

635 SMAP (Soil Moisture Active Passive) is a NASA satellite mission that was established to help in  
636 improving weather forecasts and global drought monitoring. SMAP data products are available at  
637 different levels of processing, from Level 1 (L1; instrument measurements) to Level 4 (L4; model-  
638 derived value-added products). For this study, SMAP L3 and SMAP L4 products for measuring  
639 moisture content were used. The main difference between the two products is that SMAP L3 depends  
640 on the passive radiometer measurements, while SMAP L4 products are derived from a data assimilation  
641 system that combines the L-band brightness temperature observations from SMAP with a land surface  
642 model and meteorological forcing data (Reichle, et al., 2019). SMAP L3 products for moisture content  
643 are primarily affected by vegetation and surface roughness, allowing them to capture surface soil  
644 moisture variations. In contrast, the incorporation of land surface models in SMAP L4 products reduces  
645 its sensitivity to vegetation covers and surface roughness, making the products more representative of  
646 the profile soil moisture conditions (Reichle, et al., 2019); Uela, Wood, & Sadri, 2018).

647 The autoencoder's encoded representations offer a unique opportunity to compare the spatial patterns  
648 inherent in "point measurement" with remote sensing data such as SMAP L3 and SMAP L4 data. The  
649 autoencoder method could illuminate how these diverse data streams align or diverge, providing crucial

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

Formatted: Font color: Black

650 insights into the compatibility and complementarity of ground and satellite measurements. The process  
651 was applied for the data between the years 2015 to 2022. All the data (SMAP L4, SMAP L3, and on-  
652 site measurements) were given to the autoencoder neural network together. Subsequently, the resulting  
653 autoencoder values were scaled. Finally, a comparison was made to show if the satellite measurements  
654 and the on-site measurements have the same measured dynamics.

655 The autoencoder analysis of SMAP L3 (figure C1) indicates that satellite measurements struggle to  
656 capture the dynamic change of the water content, as all locations yield approximately the same  
657 Autoencoder Value (AUV). In contrast, the SMAP L4 product (figure C1) exhibits fluctuations in AUV  
658 results. For instance, Stüsslingen and Matzendorf align closely with on-site measurements in terms of  
659 AUVs. However, for Hofstetten-Flüh, the SMAP L4 product indicates a very small AUV, suggesting  
660 an expected dynamic in line with a type 1 soil water retention curve (figure 6b). In contrast, on-site  
661 measurements indicate a higher AUV for Hofstetten-Flüh, suggesting a closer association with a type  
662 2 soil water retention curve. These findings underscore the imperative for developing a new  
663 methodology to calibrate satellite data in the Switzerland area. The prevalent uniformity in SMAP L3  
664 results and the notable disparities between on-site measurements and satellite data across various  
665 products highlight the need for a more refined approach to ensure accurate and reliable dynamic soil  
666 moisture assessments.

667  
 668 **Figure C1** Comparative analysis of Autoencoder Neural Network results for SMAP L3 and SMAP L4  
 669 satellite data, alongside with profile measurements. The fluctuating AUV values indicate varying  
 670 degrees of alignment with on-site measurements across different locations. Sites with forest are marked  
 671 with \*.

672 **Code and data availability**

673 The related input data for the AUC-DNN model and Python code are openly accessible under  
 674 <https://doi.org/10.5281/zenodo.10600669> and <https://doi.org/10.5281/zenodo.10602397> respectively.  
 675 The input for the autoencoder and its python codes are openly accessible under  
 676 <https://www.doi.org/10.5281/zenodo.10605108>

677 **Author contributions**

678 NA, AC, and PL designed the research. NA and PL performed the research. NA and MR analyzed the  
 679 soil moisture time series. SM was responsible for the soil moisture network. NA wrote the codes and  
 680 built the model. NA and PL wrote the manuscript with substantial input from all co-authors.

681 **Competing interests**

682 The contact author has declared that none of the authors has any competing interests.

## 683 Financial support

684 “This research is part of the project Artificial Intelligence for Soil Health. Funded by the European  
685 Union. Views and opinions expressed are however those of the author(s) only and do not necessarily  
686 reflect those of the European Union or of the Research Executive Agency (REA). Neither the European  
687 Union nor the granting authority can be held responsible for them.”

## 688 Acknowledgements

689 NA acknowledges the utilization of ChatGPT to enhance coherence within certain sections of the  
690 manuscript.
