

## Author's Response to Referees

### Measurement report: In-flight and ground-based measurements of nitrogen oxide emissions from latest generation jet engines and 100% sustainable aviation fuel

Report #1, Submitted on 18 Aug 2024

#### Anonymous referee #3:

The measurements reported in this manuscript are important. The authors have reasonably addressed most of the comments/concerns raised except one on NO<sub>y</sub> vs NO<sub>x</sub> by reviewer #1.

RC1 comment 1: "A clarification is needed what is measured and reported in the specific sections and plots. From my understanding for all altitude measurements NO<sub>y</sub> is measured and reported for all ground level measurements NO<sub>x</sub> is reported. Since NO<sub>x</sub> ≠ NO<sub>y</sub> even at the engine exit (HONO can make up 6% fraction e.g. [dx.doi.org/10.1021/es200921t](https://doi.org/10.1021/es200921t)) the actual reported data needs to be better described (or not labelled as NO<sub>x</sub>) throughout the manuscript. Maybe I misunderstood, but also then it needs a clarification."

In the response, the authors confirmed that NO<sub>y</sub> was measured for both in-flight and ground level measurements. They explained that "the emission indices for NO<sub>x</sub> are calculated by using the NO<sub>y</sub> concentration and the molar mass of NO<sub>2</sub>, assuming that only a small fraction of NO<sub>x</sub> is reacting to other reactive nitrogen oxides." The HONO/NO<sub>y</sub> fraction can be up to 6% based on Lee et al. (2011) and up to 3.6% according to Jurkat et al. (2011). The authors' calculation basically assumes NO<sub>x</sub>=NO<sub>y</sub> (Equ. 1), and they justify this by arguing that "fractions of HONO or HNO<sub>3</sub> are assumed to be below the total uncertainty for in-flight EI(NO<sub>x</sub>) of 14%." The authors acknowledged that "by using NO<sub>y</sub> instead of NO<sub>x</sub>, EI(NO<sub>x</sub>) might be slightly overestimated."

It is unclear to me what is the NO<sub>x</sub>/NO<sub>y</sub> ratio for the engine studied in this study and how the ratio may vary with power setting (and fuel types). Since NO<sub>y</sub> was measured and this is a measurement report manuscript, I think that it is more appropriate to report the measured values as NO<sub>y</sub>. The authors can point out in the abstract and main text that NO<sub>x</sub> is expected to be close to NO<sub>y</sub> and the uncertainty/underestimation induced by treating NO<sub>y</sub> as NO<sub>x</sub> is likely small and within the measurement uncertainty.

#### Answer to Comment:

First of all, we like to thank the referee for his comment. Unfortunately, the NO<sub>x</sub>/NO<sub>y</sub> ratio cannot be determined with the methods used during ECLIF3 and we cannot determine how the ratio may vary with power setting or fuel types. In the paper, we always use NO<sub>y</sub> when relating to the measured species and EI(NO<sub>x</sub>) when we talk about the emission index as we specifically calculated the emission index from the NO<sub>2</sub> molar mass according to definition. We hope the wording is very precise enough in this way.

To make it clearer and more understandable what is measured and how EI(NO<sub>x</sub>) is calculated, we added following sentence to section 2.1 In-flight NO<sub>y</sub> and CO<sub>2</sub> measurement methods during ECLIF3, line 84: "The instrument offers no measurement of NO<sub>x</sub> or the NO<sub>x</sub>/NO<sub>y</sub> ratio."

And we added following explanation to section 2.4 Emission index calculation and plume definition, line 189: "During ECLIF3, only NO<sub>y</sub> and no NO<sub>x</sub> concentrations were measured aboard the Falcon. NO<sub>x</sub> concentrations are expected to be close to NO<sub>y</sub> and the fraction of nitrogen acids in the exhaust gas is

assumed to be smaller than the NO<sub>y</sub> mean measurement accuracy. Hence, all reactive nitrogen species in the exhaust are detected and related to the initial NO<sub>x</sub> emissions.”
