## 14 15 **Abstract**

16 Water-soluble components have significant contribution to the oxidative  
17 potential (OP) of atmospheric fine particles (PM<sub>2.5</sub>), while our understanding of  
18 water-soluble PM<sub>2.5</sub> OP and its sources, as well as its relationship with water-soluble  
19 components, is still limited. In this study, the water-soluble OP levels in wintertime  
20 PM<sub>2.5</sub> in the south and north of Beijing, representing the difference in sources, were  
21 measured with dithiothreitol (DTT) assay. The volume normalized DTT (DTT<sub>v</sub>) in the  
22 north ( $3.5 \pm 1.2 \text{ nmol min}^{-1} \text{ m}^{-3}$ ) was comparable to that in the south ( $3.9 \pm 0.9 \text{ nmol}$   
23  $\text{min}^{-1} \text{ m}^{-3}$ ), while the mass normalized DTT (DTT<sub>m</sub>) in the north ( $65 \pm 28 \text{ pmol min}^{-1}$   
24  $\mu\text{g}^{-3}$ ) was almost twice that in the south ( $36 \pm 14 \text{ pmol min}^{-1} \mu\text{g}^{-3}$ ). In both the south  
25 and north of Beijing, DTT<sub>v</sub> was better correlated with soluble elements instead of total  
26 elements. In the north, soluble elements (mainly Mn, Co, Ni, Zn, As, Cd and Pb) and  
27 water-soluble organic compounds, especially light-absorbing compounds (also known  
28 as brown carbon), had positive correlations with DTT<sub>v</sub>. However, in the south, the

29 DTT<sub>v</sub> was mainly related to soluble As, Fe and Pb. The sources of DTT<sub>v</sub> were further  
30 resolved using the positive matrix factorization (PMF) model. Traffic-related  
31 emissions (39%) and biomass burning (25%) were the main sources of DTT<sub>v</sub> in the  
32 south, and traffic-related emissions (> 50%) contributed the most of DTT<sub>v</sub> in the north.  
33 Our results indicate that vehicle emission was the important contributor to OP in  
34 Beijing ambient PM<sub>2.5</sub> and suggest that more study is needed to understand the  
35 intrinsic relationship between OP and light absorbing organic compounds.

36

## 37 **1 Introduction**

38 Atmospheric fine particulate matter (PM<sub>2.5</sub>) pollution is one of the major global  
39 environmental issues, affecting air quality, climate and human health (Huang et al.,  
40 2014; Burnett et al., 2018; An et al., 2019; Zheng et al., 2020). The exposure to PM<sub>2.5</sub>  
41 was estimated to be responsible for 8.9 million deaths worldwide in 2015, of which  
42 28% occurred in China (Burnett et al., 2018). Numerous studies have shown that  
43 oxidative stress is one of the main mechanisms underlying the adverse effects of  
44 PM<sub>2.5</sub> on human health (Chowdhury et al., 2019; Lelieveld et al., 2021; Yu et al.,  
45 2022b). When entering the human body, PM<sub>2.5</sub> can induce the production of excessive  
46 reactive oxygen species (ROS) (e.g., H<sub>2</sub>O<sub>2</sub>, ·OH and ·O<sub>2</sub><sup>-</sup>), leading to cellular redox  
47 imbalance and generating oxidative stress effects. The ability of PM<sub>2.5</sub> to cause  
48 oxidative stress is defined as oxidative potential (OP).

49 The methods to determine the OP of PM<sub>2.5</sub> include cellular and acellular assays,  
50 and acellular methods are more widely used than cellular methods (Charrier and  
51 Anastasio, 2012; Xiong et al., 2017; Calas et al., 2018; Bates et al., 2019; Wang et al.,  
52 2020b; Campbell et al., 2021; Oh et al., 2023). Among acellular methods, the  
53 dithiothreitol (DTT) assay is extensively applied to determine the OP of ambient  
54 particles (Charrier and Anastasio, 2012; Xiong et al., 2017; Liu et al., 2018; Wang et  
55 al., 2020b; Puthussery et al., 2022; Wu et al., 2022a). DTT is a surrogate of cellular  
56 reductants, and the consumption rate of DTT was used to assess the OP of PM<sub>2.5</sub>.  
57 Previous studies have shown that organic matters (e.g., water-soluble organic species

58 and PAHs) and some transition metals (e.g., Mn and Cu) are the important  
59 contributors to DTT consumption of PM<sub>2.5</sub> (Charrier and Anastasio, 2012; Verma et  
60 al., 2015; Bates et al., 2019; Wu et al., 2022a; Wu et al., 2022b). For example,  
61 Charrier and Anastasio (2012) measured the OP of PM<sub>2.5</sub> in San Joaquin Valley,  
62 California and reported that about 80% of DTT consumption was contributed by  
63 transition metals. Verma et al. (2015) measured the OP of water-soluble PM<sub>2.5</sub> in the  
64 southeastern United States and reported that about 60% of DTT activity was  
65 contributed by water-soluble organics. The mixtures of metals and organics may  
66 produce synergistic or antagonistic effects, such as  $\cdot\text{O}_2^-$  produced from oxidation of  
67 DTT by quinones is more efficiently transformed to  $\cdot\text{OH}$  in the presence of Fe, while  
68 the DTT consumption and  $\cdot\text{OH}$  generation of quinones are reduced in the presence of  
69 Cu (Xiong et al., 2017; Yu et al., 2018; Bates et al., 2019).

70 A number of studies have investigated the OP of water-soluble components in  
71 PM<sub>2.5</sub>, which show that the average water-soluble OP values in urban areas ranged  
72 from 0.1 to 10 nmol min<sup>-1</sup> m<sup>-3</sup> (Fang et al., 2016; Liu et al., 2018; Chen et al., 2019;  
73 Wu et al., 2022a; Yu et al., 2022a; Xing et al., 2023). Due to the complexity in  
74 chemical composition and sources of PM<sub>2.5</sub> that determine the OP levels, the sources  
75 of OP are also diverse (Verma et al., 2015; Bates et al., 2019; Tuet et al., 2019; Yu et  
76 al., 2019; Cao et al., 2021). Several studies have investigated the emission sources and  
77 ambient samples to identify the sources of OP (Tuet et al., 2019; Yu et al., 2019; Wang  
78 et al., 2020b; Cao et al., 2021), which include both primary and secondary sources.  
79 For example, Cao et al. (2021) measured the water-soluble OP of PM<sub>2.5</sub> samples from  
80 six biomass and five coal burning emissions in China, with average values of 4.5-7.4  
81 and 0.5-2.1 pmol min<sup>-1</sup> μg<sup>-1</sup>, respectively. Tong et al. (2018) investigated the OP of  
82 secondary organic aerosols (SOA) from oxidation of naphthalene, isoprene and β-  
83 pinene with  $\cdot\text{OH}$  or O<sub>3</sub>, which were 104 ± 7.6, 48 ± 7.9 and 36 ± 3.1 pmol min<sup>-1</sup> μg<sup>-1</sup>,  
84 respectively. Verma et al. (2014) identified the sources of water-soluble OP of PM<sub>2.5</sub>  
85 in Atlanta, United States from June 2012 to September 2013 with positive matrix  
86 factorization (PMF) and chemical mass balance (CMB) methods, of which biomass

87 burning was the largest contributor. Wang et al. (2020b) quantified the sources of  
88 water-soluble OP of PM<sub>2.5</sub> in Xi'an, China in 2017 using PMF and multiple linear  
89 regression (MLR) methods, with significant contributions from secondary sulfates,  
90 vehicle emissions and coal combustion. Despite these efforts, comparative studies on  
91 the differences in pollution levels and sources of PM<sub>2.5</sub> OP in different districts are  
92 still limited.

93 In this study, the DTT activity of water-soluble matter in PM<sub>2.5</sub> samples collected  
94 simultaneously in the southern and northern of Beijing in January 2018 were  
95 measured. The concentration and light absorption of water-soluble organic carbon  
96 (WSOC), as well as the concentrations of 14 trace elements and 7 light-absorbing  
97 nitroaromatic compounds (NACs) were quantified. The sources of DTT activity were  
98 then identified with PMF model. The results acquired in this study provide a  
99 comparison of PM<sub>2.5</sub> OP in different districts of Beijing and its connection with  
100 organic compounds, trace elements and sources, which could be helpful for further  
101 study of the regional differences in the effects of PM<sub>2.5</sub> on human health.

102

## 103 **2 Materials and methods**

### 104 **2.1 Sampling**

105 Ambient 24 h integrated PM<sub>2.5</sub> filter samples were collected from January 1 to 31,  
106 2018 simultaneously in the south (the Dingfuzhuang village (DFZ), Daxing district;  
107 39.61°N, 116.28°E) and north (the National Center for Nanoscience and Technology  
108 (NCNT), Haidian district; 39.99°N, 116.32°E) of Beijing (Figure S1). The distance  
109 between the two sampling sites is about 42 km. The south site is surrounded by  
110 agricultural, industrial, and transportation areas, and the north site is surrounded by  
111 residential, transportation and commercial areas. PM<sub>2.5</sub> samples were collected on pre-  
112 baked (780 °C, 3 h) quartz-fiber filters (20.3 × 25.4 cm; Whatman, QM-A, Clifton, NJ,  
113 USA) using high-volume PM<sub>2.5</sub> samplers (1.13 m<sup>-3</sup> min<sup>-1</sup>; Tisch, Cleveland, OH, USA)  
114 which were placed on the roof of buildings at heights of about 5 m (south) and 20 m  
115 (north) above the ground. 31 samples were collected at each site. After collection, the

116 samples were wrapped in baked aluminum foils and stored in a freezer ( $-20\text{ }^{\circ}\text{C}$ ) until  
117 further analysis.

## 118 **2.2 Chemical analysis**

119 The mass of  $\text{PM}_{2.5}$  on the filter was measured by a digital microbalance with a  
120 precision of 0.1 mg (LA130S-F, Sartorius, Germany) after 24-h equilibration at a  
121 constant temperature ( $20\text{-}23\text{ }^{\circ}\text{C}$ ) and humidity (35-45%) chamber. Each filter was  
122 weighted at least two times, and the deviations for blank and sampled filters among  
123 the repetitions were less than 5 and 10  $\mu\text{g}$ , respectively. The  $\text{PM}_{2.5}$  mass concentration  
124 was calculated by dividing the weight difference before and after sampling by the  
125 volume of sampled air.

126 For WSOC analysis, one punch ( $1.5\text{ cm}^2$  for concentration analysis and  $0.526$   
127  $\text{cm}^2$  for light absorption measurement) of filter was taken from each sample and  
128 extracted ultrasonically with ultrapure water ( $> 18.2\text{ M}\Omega\text{ cm}$ ) for 30 min. After, the  
129 extracts were filtered with a  $0.45\text{ }\mu\text{m}$  PVDF pore syring filter to remove insoluble  
130 substances. Finally, the concentration of WSOC was measured with a total organic  
131 carbon-total nitrogen analyzer (TOC-L, Shimadzu, Japan; (Ho et al., 2015)) and the  
132 light absorption of WSOC was measured by an UV-Vis spectrophotometer ( $300\text{-}700$   
133 nm; Ocean Optics, USA) equipped with a liquid waveguide capillary cell (LWCC-  
134 3100, World Precision Instruments, Sarasota, FL, USA; (Yuan et al., 2020)). The  
135 absorption coefficient (Abs) of WSOC was calculated according to formula S1 in the  
136 Supporting Information (SI).

137 The total concentration and soluble fraction concentration of 14 trace elements  
138 (i.e., Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn, As, Sr, Cd, Ba, and Pb) were quantified by an  
139 inductively coupled plasma mass spectrometer (ICP-MS, 7700x, Agilent Technologies,  
140 USA), and the details are shown in the SI. For soluble fraction concentration analysis,  
141 a punch of filter ( $47\text{ mm}$  diameter) was extracted with ultrapure water and then  
142 centrifuged from residues. For total concentration analysis, another  $47\text{ mm}$  diameter  
143 filter of the same sample was used and digested with  $10\text{ mL HNO}_3$  and  $1\text{ mL HF}$  at  
144  $180\text{ }^{\circ}\text{C}$  for 12 h. The extracts were then heated and concentrated to  $\sim 0.1\text{ mL}$ , and

145 diluted to 5 mL with 2% HNO<sub>3</sub>. Afterwards, the diluents were filtered with a 0.22 μm  
146 PTFE pore syring filter and stored in a freezer (−4 °C) until further ICP-MS analysis.

147 The concentrations of organic markers (including levoglucosan, mannosan,  
148 galactosan, hopanes (including 17α(H)-22,29,30-trisnorhopane, 17α(H),21β(H)-30-  
149 norhopane, 17β(H),21α(H)-30-norhopane, 17β(H),21α(H)-hopane, 17β(H),21α(H)-  
150 hopane and 17β(H),21α(H)-hopane), picene, phthalic acid, isophthalic acid and  
151 terephthalic acid) and light-absorbing NACs (including 4-nitrophenol (4NP), 2-  
152 methyl-4-nitrophenol (2M4NP), 3-methyl-4-nitrophenol (3M4NP), 4-nitrocatechol  
153 (4NC), 3-methyl-5-nitrocatechol (3M5NC), 4-methyl-5-nitrocatechol (4M5NC) and  
154 4-nitro-1-naphthol (4N1N)) were determined by a gas chromatograph–mass  
155 spectrometer (GC-MS; Agilent Technologies, Santa Clara, CA, USA) following the  
156 method described elsewhere (Wang et al., 2020a), and more details about the analysis  
157 can be found in SI. All of the results reported in this study were corrected for blanks.

### 158 **2.3 Oxidative potential**

159 The DTT assay was applied to determine the oxidative potential of water-soluble  
160 components in PM<sub>2.5</sub> according to the method by Gao et al. (2017). In brief, a quarter  
161 of a 47 mm filter was ultrasonically extracted with 5 mL ultrapure water for 30 min  
162 and then filtered with a 0.45 μm PVDF pore syring filter to remove insoluble  
163 substances. Several studies have shown that ultrasonic treatment of samples can lead  
164 to an increase in their OP values (Miljevic et al., 2014; Jiang et al., 2019), however,  
165 there was also a study showed that the difference in OP values of water-soluble PM<sub>2.5</sub>  
166 measured by DTT assay was little for samples extracted by ultrasonic and shaking  
167 (Gao et al., 2017). Consistent with the extraction methods for organic markers and  
168 trace elements, ultrasonic method was used to extract samples for DTT analysis.  
169 Afterwards, 0.5 mL of the extract was mixed with 1 mL of potassium phosphate  
170 buffer (pH = 7.4) and 0.5 mL of 2 mM DTT in a brown vial, and then placed in a  
171 water bath at 37 °C. Then, 20 μL of this mixture was taken at designated time  
172 intervals (2, 7, 13, 20, and 28 min) and mixed with 1 mL trichloroacetic acid (TCA;  
173 1% w/v) in another brown vial to terminate the reaction. Then, 0.5 mL of 5,5'-

174 dithiobis-(2-nitrobenzoic acid) (DTNB; 2.5  $\mu\text{M}$ ) and 2 mL of tris buffer (pH = 8.9)  
175 were added to form 2-nitro-5-thiobenzonic acid (TNB) which has light absorption at  
176 412 nm. Finally, the absorption of TNB was measured by a LWCC-UV-Vis. The DTT  
177 consumption rate was quantified by the remaining DTT concentration at different  
178 reaction times. Daily solution blanks and filter blanks were analyzed in parallel with  
179 samples to evaluate the consistency of the system performance. Besides, for every 10  
180 samples, one sample was chosen to be measured three times to check the  
181 reproducibility, and the relative standard deviation was lower than 5%. Ambient  
182 samples were corrected for filter blank. The DTT activities were normalized by the  
183 volume of sampled air ( $\text{DTT}_v$ ,  $\text{nmol min}^{-1} \text{m}^{-3}$ ) and the mass concentration of  $\text{PM}_{2.5}$   
184 ( $\text{DTT}_m$ ,  $\text{pmol min}^{-1} \mu\text{g}^{-1}$ ).

185 Considering that for samples containing a significant amount of substances  
186 whose DTT response is non-linear with  $\text{PM}_{2.5}$  concentration (e.g., Cu, Mn), the  $\text{DTT}_m$   
187 value depends on the concentration of  $\text{PM}_{2.5}$  added to the reaction solution (Charrier  
188 et al., 2016). The response of  $\text{DTT}_m$  to  $\text{PM}_{2.5}$  concentration added to the reaction  
189 solution was analyzed using sample containing high concentrations of soluble Cu and  
190 Mn (Figure S2). When the  $\text{PM}_{2.5}$  concentration added to the reaction solution is less  
191 than  $150 \mu\text{g mL}^{-1}$ , the  $\text{DTT}_m$  response is greatly affected by the difference in added  
192  $\text{PM}_{2.5}$  concentration; however, when the  $\text{PM}_{2.5}$  concentration added to the reaction  
193 solution is greater than  $150 \mu\text{g mL}^{-1}$ , the  $\text{DTT}_m$  response is less affected by the  
194 difference in  $\text{PM}_{2.5}$  concentration ( $< 12\%$ ). In this study, the concentration of  $\text{PM}_{2.5}$   
195 added to the reaction solution of most samples from the two sites was greater than  $150$   
196  $\mu\text{g mL}^{-1}$  (ranged from 79 to  $749 \mu\text{g mL}^{-1}$ , with an average of  $409 \pm 164$  and  $207 \pm 95$   
197  $\mu\text{g mL}^{-1}$  in the south and north, respectively), therefore, the difference in  $\text{PM}_{2.5}$   
198 concentration added to the reaction solution of different samples should had a  
199 relatively small impact on the difference in  $\text{DTT}_m$  values of different samples. This  
200 study did not consider the impact of metal precipitation in phosphate matrix on the  
201 measured DTT values, as there is not a straightforward method to correct the artifact  
202 caused by this phenomenon (Yalamanchili et al., 2023).

## 203 **2.4 Source apportionment**

204 The sources of DTT activities were identified and quantified using PMF model  
205 implemented by the multilinear engine (ME-2; (Paatero, 1997)) following the method  
206 described in our previous studies (Huang et al., 2014; Yuan et al., 2020). For each site,  
207 31 samples and 23 species were input into PMF model. The number of samples is  
208 higher than the number of species. The input data include species concentration  
209 (including DTT<sub>v</sub>, 14 trace elements and 8 organic markers) and uncertainties. The  
210 species-specific uncertainties were calculated following Liu et al. (2017). More details  
211 are described in SI (PMF analysis).

212

## 213 **3 Results and discussion**

### 214 **3.1 DTT activity and concentrations of water-soluble PM<sub>2.5</sub> components**

215 Figure 1 shows the daily variation of DTT activity, light absorption of WSOC at  
216 wavelength 365 nm (Abs<sub>365</sub>), together with the concentrations of PM<sub>2.5</sub>, WSOC,  
217 NACs and total elements in the south and north of Beijing. Their average values are  
218 shown in Table S1. Generally, the average values of PM<sub>2.5</sub>, WSOC, Abs<sub>365</sub>, NACs and  
219 total elements were higher in the south than in the north. Specifically, the  
220 concentrations of PM<sub>2.5</sub> and WSOC in the south ( $122 \pm 49 \mu\text{g m}^{-3}$  and  $8.1 \pm 5.0 \mu\text{gC}$   
221  $\text{m}^{-3}$ , respectively) were both about two times higher than that in the north ( $62 \pm 28 \mu\text{g}$   
222  $\text{m}^{-3}$  and  $4.0 \pm 2.0 \mu\text{gC m}^{-3}$ , respectively), indicating that the proportion of WSOC in  
223 PM<sub>2.5</sub> was similar in the south and north. However, the Abs<sub>365</sub> in the south was about  
224 three times that in the north, indicating that the chemical composition of WSOC was  
225 different between the south and north. Previous studies have reported that NACs are  
226 the main water-soluble light-absorbing organic compounds (also known as brown  
227 carbon, BrC) of PM<sub>2.5</sub> (Lin et al., 2017; Huang et al., 2020; Li et al., 2020). For the 7  
228 NACs quantified in this study, the total concentration of nitrophenols (4NP, 2M4NP  
229 and 3M4NP), nitrocatechols (4NC, 3M5NC and 4M5NC), and 4N1N in the south  
230 ( $108 \pm 73 \text{ ng m}^{-3}$ ,  $118 \pm 91 \text{ ng m}^{-3}$  and  $12 \pm 8.2 \text{ ng m}^{-3}$ , respectively) was about three,  
231 five and four times, respectively, those in the north ( $35 \pm 22 \text{ ng m}^{-3}$ ,  $24 \pm 30 \text{ ng m}^{-3}$

232 and  $3.1 \pm 3.0 \text{ ng m}^{-3}$ , respectively). These results indicate that the sources and  
233 emission strength of water-soluble organic compounds were different in the south and  
234 north of Beijing, suggesting the different contribution of water-soluble organic  
235 compounds to DTT activity. The concentration trends of trace elements were also  
236 different between the south and north of Beijing, with  $\text{Fe} > \text{Zn} > \text{Ti} > \text{Mn} > \text{Cu} > \text{Ba} >$   
237  $\text{Pb} > \text{Sr} > \text{Cr} > \text{As} > \text{V} > \text{Ni} > \text{Cd} > \text{Co}$  in the south, and  $\text{Fe} > \text{Ti} > \text{Zn} > \text{Ba} > \text{Mn} >$   
238  $\text{Pb} > \text{Cu} > \text{Cr} > \text{Sr} > \text{As} > \text{Ni} > \text{V} > \text{Cd} > \text{Co}$  in the north. It should be noted that  
239 although the contents of  $\text{PM}_{2.5}$ , WSOC and total elements measured in this study were  
240 higher in the south than in the north, the average  $\text{DTT}_v$  value in the south ( $3.9 \pm 0.9$   
241  $\text{nmol min}^{-1} \text{ m}^{-3}$ ) was comparable to that in the north ( $3.5 \pm 1.2 \text{ nmol min}^{-1} \text{ m}^{-3}$ ),  
242 meanwhile, the average  $\text{DTT}_m$  value was much higher (1.8 times) in the north ( $65 \pm$   
243  $28 \text{ pmol min}^{-1} \mu\text{g}^{-1}$ ) than in the south ( $36 \pm 14 \text{ pmol min}^{-1} \mu\text{g}^{-1}$ ). The lower  $\text{DTT}_m$  in  
244 the south than in the north may be due to the increased  $\text{PM}_{2.5}$  in the south containing  
245 more substances with no or little contribution to DTT activity, and indicates that the  
246 intrinsic OP of water-soluble components of  $\text{PM}_{2.5}$  was higher in the north than in the  
247 south. The similar  $\text{DTT}_v$  values in the south and north indicate that the exposure-  
248 relevant OP of water-soluble components of  $\text{PM}_{2.5}$  was comparable in the two sites,  
249 and the water-soluble  $\text{DTT}_v$  was not consistent with the content of water-soluble  
250 substances.

251 Figure 2 shows the comparison of water-soluble  $\text{PM}_{2.5}$  DTT activity measured in  
252 this study with those measured in other regions of Asia during similar periods. It can  
253 be seen that the  $\text{DTT}_v$  values measured in Beijing in this study were lower than that in  
254 Jinzhou, Tianjin, Yantai, and Shanghai in China, Lahore and Peshawar in Pakistan,  
255 and Delhi in India (Liu et al., 2018; Ahmad et al., 2021; Puthussery et al., 2022; Wu et  
256 al., 2022a), higher than that in Xi'an, Nanjing, Hangzhou, Guangzhou, and Shenzhen  
257 in China (Wang et al., 2019; Wang et al., 2020b; Ma et al., 2021; Yu et al., 2022c;  
258 Xing et al., 2023), and comparable with that in Ningbo, China (Chen et al., 2022).  
259 Different from  $\text{DTT}_v$ , the  $\text{DTT}_m$  value measured in NCNT in Beijing was similar with  
260 that in Jinzhou, Tianjin, Yantai, Shanghai and Ningbo in China (Liu et al., 2018; Chen

261 et al., 2022; Wu et al., 2022a), and higher than that in other regions. The differences in  
262 water-soluble DTT activity of PM<sub>2.5</sub> in different regions can be explained by the  
263 differences in chemical composition, sources and atmospheric formation processes  
264 (Tong et al., 2017; Wong et al., 2019; Daellenbach et al., 2020; Wang et al., 2020b;  
265 Cao et al., 2021). For example, Cao et al. (2021) reported the water-soluble DTT  
266 activity of PM<sub>2.5</sub> from biomass and coal burning emissions in China, and the average  
267 value of biomass burning (4.5-7.4 pmol min<sup>-1</sup> μg<sup>-1</sup>) was much higher than that of coal  
268 burning (0.5-2.1 pmol min<sup>-1</sup> μg<sup>-1</sup>). Tuet et al. (2017) measured the water-soluble DTT  
269 activity of SOA generated under different precursors and reaction conditions, with  
270 SOA from naphthalene photooxidation under RO<sub>2</sub> + NO-dominant dry reaction  
271 conditions had the highest DTT activity.

### 272 **3.2 Correlation between DTT activity and water-soluble PM<sub>2.5</sub> components**

273 Figure 3 shows the correlations of DTT<sub>v</sub> with PM<sub>2.5</sub>, WSOC and Abs<sub>365</sub> in the  
274 south and north of Beijing. It can be seen that the correlation coefficient between  
275 DTT<sub>v</sub> and PM<sub>2.5</sub> was moderate in both the south (r = 0.42) and north (r = 0.45),  
276 indicating that the toxicity of particles cannot be evaluated solely by the total PM<sub>2.5</sub>  
277 concentration. The correlations between DTT<sub>v</sub> with WSOC and Abs<sub>365</sub> were strong in  
278 the north (r of 0.69 and 0.70, respectively), while relatively weak in the south (r of  
279 0.41 and 0.40, respectively). The high correlations between DTT<sub>v</sub> with WSOC and  
280 Abs<sub>365</sub> in the north of Beijing qualitatively agree with previous studies in Xi'an, China  
281 and Atlanta, United States (Verma et al., 2012; Chen et al., 2019), and suggest that  
282 water-soluble organic matter, especially BrC, has a significant contribution to DTT  
283 consumption in the north. Light-absorbing BrC typically has conjugated electrons,  
284 making it more likely to transport electrons for catalytic reactions, thereby  
285 contributing to DTT activity (Chen et al., 2019; Wu et al., 2022). Further, in the north,  
286 the DTT<sub>v</sub> was closely related to the concentrations of NACs (r of 0.57 to 0.79) (Figure  
287 S3), suggesting that NACs may be important contributors to DTT consumption. Feng  
288 et al. (2022) reported the positive correlations between NACs and biomarkers in  
289 saliva and urine (interleukin-6 and 8-hydrox-2'-deoxyguanosine). Zhang et al. (2023)

290 also reported that NACs are major proinflammatory components in organic aerosols,  
291 contributing about 24% of the interleukin-8 response of all compounds detected by  
292 Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR-MS) in  
293 electrospray ionization negative mode (ESI-). Certainly, it may also be other  
294 substances related to NACs that contribute to the DTT activity, including those not  
295 detected in this study, driving the good correlation between NACs and DTT<sub>v</sub> in the  
296 north of Beijing, which is worth studying in the future.

297 The correlation coefficients between DTT<sub>v</sub> and 14 trace elements are shown in  
298 Figure 4. Generally, the correlations between DTT<sub>v</sub> and soluble elements were higher  
299 than that between DTT<sub>v</sub> and total elements in both the south and north of Beijing. For  
300 soluble elements, in the south, the DTT<sub>v</sub> showed positive correlations with Mn, Fe, Cr,  
301 Co, As and Pb ( $r > 0.5$ ), while in the north, it exhibited strong positive correlations  
302 with Mn, Co, Ni, Zn, As, Cd and Pb ( $r > 0.7$ ), indicating the different sources of DTT<sub>v</sub>  
303 in the south and north of Beijing. It is worth noting that the concentrations of all  
304 soluble elements were higher in the south than in the north (Figure S4), while the  
305 correlation between DTT<sub>v</sub> and most soluble elements was lower in the south than in  
306 the north (Figure 4). The high correlations between DTT<sub>v</sub> and soluble elements in the  
307 north of Beijing suggests that soluble elements also had a significant contribution to  
308 DTT consumption. The low correlations between DTT<sub>v</sub> and soluble elements in the  
309 south of Beijing may be due to the nonlinear relationship between DTT consumption  
310 and element concentration (Charrier and Anastasio, 2012; Wu et al., 2022a). As shown  
311 in Figure S5, the relationship between most soluble trace elements and DTT<sub>v</sub> was  
312 more non-linear than linear. As the concentration of soluble elements increases, the  
313 growth rate of DTT<sub>v</sub> obviously decreases.

314 In addition to being associated with individual water-soluble species, the  
315 interactions between metals and organic compounds also affect the consumption of  
316 DTT (Xiong et al., 2017; Wu et al., 2022b), with both synergistic and antagonistic  
317 effects. For example, Wu et al. (2022b) measured the DTT consumption of Fe(III) and  
318 Cu(II) interacting with 1,4-naphthoquinone, 9,10-phenanthraquinone, citric acid, and

319 4-nitrocatechol, respectively. Their results showed that Cu(II) had antagonistic effects  
320 in interacting with most organics except for citric acid, and Fe(III) had an additive  
321 effect on DTT consumption of 1,4-naphthoquinone and citric acid, while it had an  
322 antagonistic effect on 1,4-naphthoquinone and 9,10-phenanthraquinone. Due to the  
323 complex composition of water-soluble organic aerosols, the knowledge about the  
324 effects of organics and metal-organic interactions on DTT activity are still limited,  
325 especially the effects of BrC chromophores and their interactions with metals.

### 326 **3.3 Sources of DTT activity**

327 This study analyzed eight organic markers (including levoglucosan, mannosan,  
328 and galactosan for biomass burning, hopanes for vehicle emissions, picene for coal  
329 combustion, and phthalic acid, isophthalic acid and terephthalic acid for secondary  
330 formation) to help identify the sources of DTT activity. The correlation coefficients  
331 between  $DTT_v$  and organic markers are shown in Figure S6. In the south,  
332 levoglucosan, mannosan, galactosan, and hopanes had moderate correlation with  
333  $DTT_v$  (r of 0.41 to 0.48); phthalic acid, isophthalic acid and terephthalic acid had low  
334 to moderate correlation with  $DTT_v$  (r of 0.28 to 0.54); picene had low correlation with  
335  $DTT_v$  (r of 0.21). These results suggest that biomass burning and vehicle emissions  
336 could have significant contribution to water-soluble  $PM_{2.5}$  OP in the south. In the  
337 north, hopanes had the highest correlation with  $DTT_v$  ( $r = 0.70$ ), indicating that  
338 vehicle emissions could have an important contribution. Levoglucosan, mannosan,  
339 galactosan, phthalic acid, isophthalic acid, terephthalic acid, and picene had moderate  
340 to high correlations with  $DTT_v$  in the north, suggesting that biomass and coal burning,  
341 and secondary formation may also have certain contribution to water-soluble  $PM_{2.5}$   
342 OP.

343 To further quantify the sources of DTT activity in the south and the north of  
344 Beijing, the PMF model, which was widely used for the source apportionment of  
345  $PM_{2.5}$  OP (Liu et al., 2018; Shen et al., 2022; Cui et al., 2023), was applied. The input  
346 species include  $DTT_v$ , soluble elements and organic markers, and five to seven factors  
347 were examined. Due to the oil factor mixed with vehicle emissions factor in the five-

348 factor solution, and there was no new reasonable factor when increasing the factor  
349 number to seven in the PMF analysis (Figure S7). Finally, six factors were resolved  
350 and quantified using PMF model in the south and north of Beijing, including biomass  
351 burning, coal burning, traffic-related, dust, oil combustion, and secondary formation,  
352 and the profiles of these sources are shown in Figure S8. Factor 1 is characterized by  
353 high contribution of levoglucosan, mannosan, and galactosan, mainly from biomass  
354 burning (Huang et al., 2014; Chow et al., 2022). The DTT activity of biomass burning  
355 organic aerosol was measured by Wong et al. (2019), which was  $48 \pm 6 \text{ pmol min}^{-1}$   
356  $\mu\text{g}^{-1}$  of WSOC. Liu et al. (2018) quantified the sources of  $\text{DTT}_v$  in coastal cities  
357 (Jinzhou, Tianjin, and Yantai) in China with PMF model and multiple linear  
358 regression method, and the results showed that biomass burning contributed 28% on  
359 average in winter. Factor 2 exhibits a large fraction of picene, Zn, Mn, Cd, As, and Pb,  
360 which is considered to be coal burning (Huang et al., 2014; Huang et al., 2018). Joo et  
361 al. (2018) measured the DTT activity of  $\text{PM}_{2.5}$  emitted from coal combustion at  
362 different temperatures, with the highest values of  $26 \pm 21 \text{ pmol min}^{-1} \mu\text{g}^{-1}$  and  $0.10 \pm$   
363  $0.06 \text{ nmol min}^{-1} \text{ m}^{-3}$  occurring at  $550 \text{ }^\circ\text{C}$ . Factor 3 is identified as traffic-related  
364 emissions, which is characterized by the higher loading of hopanes, Ba, Sr, Cu and Ni  
365 (Huang et al., 2018; Chow et al., 2022). Vreeland et al. (2017) measured the DTT  
366 activity of  $\text{PM}_{2.5}$  emitted by side street and highway vehicles in Atlanta, with values  
367 of  $0.78 \pm 0.60 \text{ nmol min}^{-1} \text{ m}^{-3}$  and  $1.1 \pm 0.60 \text{ nmol min}^{-1} \text{ m}^{-3}$ , respectively. Ting et al.  
368 (2023) reported that the DTT activity of  $\text{PM}_{2.5}$  from vehicle emissions in Ziqing  
369 tunnel in Taiwan, China, was  $0.15\text{-}0.46 \text{ nmol min}^{-1} \text{ m}^{-3}$ . Factor 4, secondary formation,  
370 which is identified by high levels of phthalic acid, isophthalic acid, and terephthalic  
371 acid (Al-Naiema and Stone, 2017; Wang et al., 2020a). Verma et al. (2014) reported  
372 that secondary formation contributed about 30% to the water-soluble DTT activity of  
373  $\text{PM}_{2.5}$  in urban Atlanta. It is worth noting that the DTT activity of SOA generated  
374 from different precursors is different (Tuet et al., 2017; Tong et al., 2018). For  
375 example, the DTT activity of SOA from naphthalene was higher than that from  
376 isoprene (Tuet et al., 2017; Tong et al., 2018). Factor 5 is dominated by crustal

377 elements Fe and Ti, mainly from dust (Huang et al., 2018). The DTT activity of  
378 atmospheric particulate matter during dust periods were reported in previous studies  
379 (Chirizzi et al., 2017; Khoshnamvand et al., 2023) and it has a low contribution in this  
380 study. Factor 6 is identified as oil combustion because of the high levels of V and Ni  
381 (Moreno et al., 2011; Minguillón et al., 2014; Huang et al., 2018).

382 The source contributions of DTT<sub>v</sub> in the south and north of Beijing are shown in  
383 Figure 5, exhibiting obvious district differences. In the south, traffic-related emissions  
384 (39%) and biomass burning (25%) had the most contribution to DTT<sub>v</sub>, followed by  
385 secondary formation (17%), coal burning (15%), dust (2%), and oil combustion (2%).  
386 In the north, traffic-related emissions (52%) had the highest contribution to DTT<sub>v</sub>,  
387 followed by coal burning (20%), secondary formation (13%), biomass burning (8%),  
388 oil combustion (4%), and dust (3%). The absolute contribution of each source to  
389 DTT<sub>v</sub> varies by 1.2-3.4 times between the south and north of Beijing (Table S2). The  
390 large district differences in sources of DTT<sub>v</sub> of water-soluble PM<sub>2.5</sub> call for more  
391 research on the relationship between sources, chemical composition, formation  
392 processes and OP of PM<sub>2.5</sub>.

393

#### 394 **4 Conclusions**

395 In this study, the water-soluble OP of ambient PM<sub>2.5</sub> collected in winter in the  
396 south and north of Beijing were quantified, together with the concentration and light  
397 absorption of WSOC, and concentrations of 7 light-absorbing NACs and 14 trace  
398 elements. The average DTT<sub>v</sub> value was comparable in the south ( $3.9 \pm 0.9 \text{ nmol min}^{-1}$   
399  $\text{m}^{-3}$ ) and north ( $3.5 \pm 1.2 \text{ nmol min}^{-1} \text{ m}^{-3}$ ), while the DTT<sub>m</sub> was higher in the north ( $65$   
400  $\pm 28 \text{ pmol min}^{-1} \mu\text{g}^{-1}$ ) than in the south ( $36 \pm 14 \text{ pmol min}^{-1} \mu\text{g}^{-1}$ ), indicating that the  
401 exposure-relevant OP of water-soluble components of PM<sub>2.5</sub> was similar in the two  
402 sites and that the intrinsic OP of water-soluble components of PM<sub>2.5</sub> was higher in the  
403 north than in the south. The correlation between DTT<sub>v</sub> and soluble elements was  
404 higher than that between DTT<sub>v</sub> and total elements in both the south and north. In the  
405 north, the DTT<sub>v</sub> was strongly correlated with soluble Mn, Co, Ni, Zn, As, Cd and Pb

406 ( $r > 0.7$ ), and in the south it positively correlated with Mn, Fe, Cr, Co, As and Pb ( $r >$   
407 0.5). In addition, in the north the  $DTT_v$  was also positively correlated with WSOC,  
408  $Abs_{365}$  and NACs ( $r$  of 0.56 to 0.79), while in the south it was weakly correlated ( $r \leq$   
409 0.4). These results indicate that in the north trace elements and water-soluble organic  
410 compounds, especially BrC chromophores, both had significant contributions to DTT  
411 consumption, and in the south the consumption of DTT may be mainly from trace  
412 elements. Six sources of  $DTT_v$  were resolved with the PMF model, including biomass  
413 burning, coal burning, traffic-related, dust, oil combustion, and secondary formation.  
414 On average, traffic-related emissions (39%) and biomass burning (25%) were the  
415 major contributors of  $DTT_v$  in the south, and traffic-related emissions (52%) was the  
416 predominated source in the north. The differences in  $DTT_v$  sources in the south and  
417 north of Beijing suggest that the relationship between source emissions and  
418 atmospheric processes and  $PM_{2.5}$  OP deserve further exploration in order to better  
419 understand the regional differences of health impacts of  $PM_{2.5}$ .
