**Abstract:** ClimeApp is a newly developed web-based processing tool for the state-of-the-art ModE-RA paleo-climate reanalysis. It presents temperature, precipitation and pressure reconstructions with global coverage and monthly resolution for the period 1422 to 2008 C.E. These can be visualized as maps or timeseries and compared with historical or other climate-related information through composite, correlation and regression functions. ClimeApp allows access to three data sets: 1. ModE-RA, a reanalysis that is created by assimilating early instrumental documentary and proxy data into an ensemble of climate model simulations. 2. ModE-Sim, the native version of the underlying ensemble simulations, i.e. prior to data assimilation. 3. ModE-RAclim, an alternative version of the reanalysis product. ClimeApp allows access to three data sets: The ModE-RA reanalysis; the ModE-Sim climate simulation, which is the basis of ModE-RA before assimilating early instrumental, documentary and proxy data; and the sensitivity experiment ModE-RAclim. Alongside ModE-RA, ClimeApp allows access to the ModE-Sim climate simulation, which is the basis of ModE-RA before assimilating early instrumental, documentary and proxy data. Together with the sensitivity experiment ModE-RAclim, Together, these three data sets allow researchers to separate the effects of model simulations and observations on the reanalysis. external forcing from internal climate variability. The app is designed to allow quick data processing for climatologists and easy use for non-climatologists. Specifically, it aims to help bring climate into the humanities, where climatological data still has huge potential to advance research. This paper outlines the development, processing and applications of ClimeApp, and presents an updated analysis of the calamitous Tambora volcanic eruption and the 1816 ‘year without a summer’ in Europe, using the new ModE datasets.

ClimeApp is available at <https://mode-ra.unibe.ch/climeapp/>.

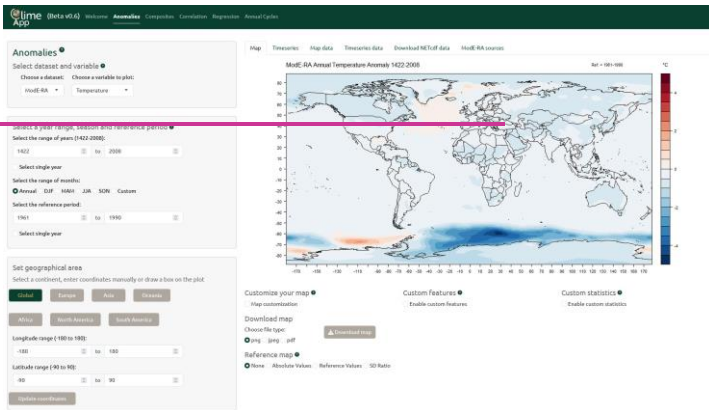

## 1 Introduction

35 Interdisciplinary research is a great facilitator of scientific progress. It allows researchers to address all aspects of  
a problem and take a holistic view not limited to one specialised field. To assess, for instance, the impact of a  
volcanic eruption such as Mount Tambora in 1815, volcanologists may study the eruption itself (Kandlbauer and  
Sparks, 2014), climatologists use numerical models to assess the climate impact (Raible et al., 2016), historians  
look into administrative records for social impacts (Krämer, 2015), and economists and epidemiologists look for  
40 effects on trade and the spread of disease (Wood, 2014). By combining their results, researchers can obtain  
unique insights relevant to all fields, as demonstrated by Brönnimann and Krämer (2016). To bridge disciplines  
as different as history and climate science, it is crucial to make data accessible to non-specialists. ClimeApp is a  
web-based application that achieves this by giving researchers without a climatology background the possibility  
to add climate reconstruction data to their sources and analysis. It facilitates quick and easy processing of the  
45 ModE-RA climate reanalysis and associated datasets (Valler et al., 2024), allowing both climatologists and other  
researchers to evaluate the data without time-consuming coding. Functions for both casual investigation, as well  
as detailed statistical and source analysis, are built in. It is also possible to upload your own research – be it  
prices, harvest yields or mortality – as a timeseries to compare with the ModE-RA dataset. ClimeApp, developed  
using the Shiny R package (Chang et al., 2024), stands out for its simplicity and accessibility in presenting and  
50 processing complex data. This paper summarises the ModE-RA, ModE-Sim and ModE-RAclim datasets used in  
ClimeApp and outlines the main features of ClimeApp’s internal structure and external interface. We then  
examine the 1815 Tambora eruption and the following ‘year without a summer’ in Europe to showcase the  
functions and applications of both ClimeApp and the ModE data. This demonstrates how reanalysis data can be  
used to distinguish between internally and externally forced variability of the climate system. We conclude by  
55 expanding on the app’s potential for both the humanities and climate sciences. Detailed reference material for  
ClimeApp data processing can be found in the appendices.

## 2 Data Sets

### 2.1 ModE-Sim

70 ModE-Sim is an ensemble of global climate simulations, driven by external forcings. The ensemble is produced by inputting reconstructed volcanic aerosols, total solar irradiation and greenhouse gases into the ECHAM6 atmosphere general circulation model (Stevens et al., 2013), with observed/reconstructed sea surface temperature (SST) and sea ice acting as boundary conditions. The different ensemble members are produced by using different versions of the SST and volcanic forcings, which accounts for the uncertainty in the reconstructions.

75 Each member in the ModE-Sim ensemble therefore represents a possible climate state that is physically compatible (from the model's perspective) with the prescribed external forcings and boundary conditions (Hand et al., 2023). The ModE-Sim ensemble resulting output, which is the forms part of the physical basis/prior for ModE-RA (see below), is therefore a combination of externally forced signals and internal variability predicted by the model physics. The ModE-Sim ensemble mean, used by ClimeApp, is the average over all ensemble

80 members. Averaging tends to "smooth out" ~~some~~ most of the internal variability, but does retain signals caused by external forcing, e.g. the climate's reaction to a volcanic eruption. ModE-Sim is a climate model experiment that provides a range of physically consistent representations of the past global climate (Hand et al., 2023). Originally designed to form the physical basis for ModE-RA, it is a medium-size ensemble of model simulations using the ECHAM6 atmosphere general circulation model (Stevens et al., 2013). The model uses reconstructed

85 volcanic aerosols, total solar irradiation and greenhouse gases as external forcings, while observed/reconstructed sea surface temperature and sea ice act as boundary conditions. The ModE-Sim ensemble mean used in ClimeApp represents the average over a set of climate states (the "ensemble members") that the model assumes to be realistic given the external forcings and boundary conditions. Averaging reduces temporal variability in the ensemble mean, compared with observations, but retains and highlights signals caused by variations in the

90 forcings and boundary conditions, e.g. the climate's reaction to a volcanic eruption. On its own, ModE-Sim can be used as a tool to study climate variability, but in combination with ModE-RA it can also help climatologists identify how observations affect the final reanalysis (see our case study, section 4.1).

## 2.2 ModE-RA

At the time of writing, the Modern Era Reanalysis (ModE-RA) is the most comprehensive reconstruction of the monthly global climate of the past 600 years (Valler et al., 2024). By assimilating a huge database of climate observations, each ModE-Sim ensemble member is corrected/updated towards the observations, weighted by individual uncertainties in both observations and simulations, respectively. In ModE-RA therefore, the effects of both external forcing and internal variation arise from a combination of the simulations and assimilated observations and ModE-Sim's climate models. Climate observations are assimilated biannually for each year. The number of observations increases rapidly exponentially through time, rising from a few thousand natural proxies and historical documents in the 15<sup>th</sup> century to over 100,000 (mostly instrumental) measurements by the early 20<sup>th</sup> century. These climate observations are assimilated biannually for each year by the late 19<sup>th</sup> century approximately 100,000 mostly instrumental measurements are assimilated each year. Natural proxies include tree rings, ice cores, corals, speleothems and lake sediments, while historical proxies are gathered from weather diaries, phenological data and early ship records. Where and when records are data is available, this allows observation-based accurate reconstruction of all four seasons, the autumn, winter and spring seasons, improving on previous studies which mostly tended to focussed on in addition to the widespread tree-ring based summer reconstructions the summer season. If no observations are available, ModE-RA relies on the climate predictions of identical to ModE-Sim. Note that while the ensemble mean of ModE-Sim mainly represents the model's response to external forcings, but the assimilation of observations into ModE-RA brings back internal variability. This is also the reason for. This also means that there is increasing variability in the ModE-RA ensemble mean over time (as the number of observations increases) with the increasing number of observations. The current spatial horizontal resolution for ModE-RA is 1.875° (longitude) by 1.865° (latitude), while the temporal resolution is one month.

## 2.3 ModE-RAclim

ModE-RAclim (Valler et al., 2024) is an alternative version of ModE-RA, designed to focus on the observations, by minimising its input from the ModE-Sim climate models. In ModE-RA, observations are assimilated into time-aligned ensemble members from ModE-Sim (i.e. for the year 1800, the basis for ModE-RA is the externally simulated forced ModE-Sim states for 1800). By contrast for each year, ModE-RAclim uses the same assimilation process (see Valler et al., 2024; for more detail), but using non-time-aligned ModE-Sim members. Instead, for each year, a random sample of 100 years from any of the ModE-Sim / and ensemble members from ModE-Sim is used to form the ModE-RAclim ensemble, prior to assimilation, with the selected year being the one that best matches the observations. This means in times and regions without any observations the resulting anomalies will be close to a zero, i.e. climatology, starts with 100 randomly picked years from ModE-Sim before assimilating observations. ModE-RA, by contrast, starts with an ensemble of predictions, specific to that year. This means that in ModE-RAclim, the externally forced signal in the model simulations is removed from the ensemble and only added back if it appears in the observations. Hence, following To give an example: Following a volcanic eruption, ModE-RA and ModE-Sim will both include the model response to stratospheric subsequent aerosol forcing, but while any volcanic signal in ModE-RAclim will exclusively result from the observations.

model response to the external forcings and boundary conditions- ModE-RAclim The comparison is therefore hence useful for distinguishing whether observed climate anomalies are a consequence of the external forcing that was used for- the model simulations or a result of data assimilation (see our case study, section 4.1).

### 3 Interface

#### 3.1 Building a Shiny app – User Interface (UI), Server and Helpers

R Shiny Apps have become popular not only for research in general (Gebauer et al., 2023) but particularly in climate science. They provide a powerful set of tools for quickly creating and deploying simple applications for presenting or processing data. Other scientific applications designed using R Shiny are described in: (Sousa, 2019; Fajardo et al., 2020; Möller et al., 2020). There are three main components to a Shiny app: The local server where all the necessary data is stored, the R environment and the web interface.

140

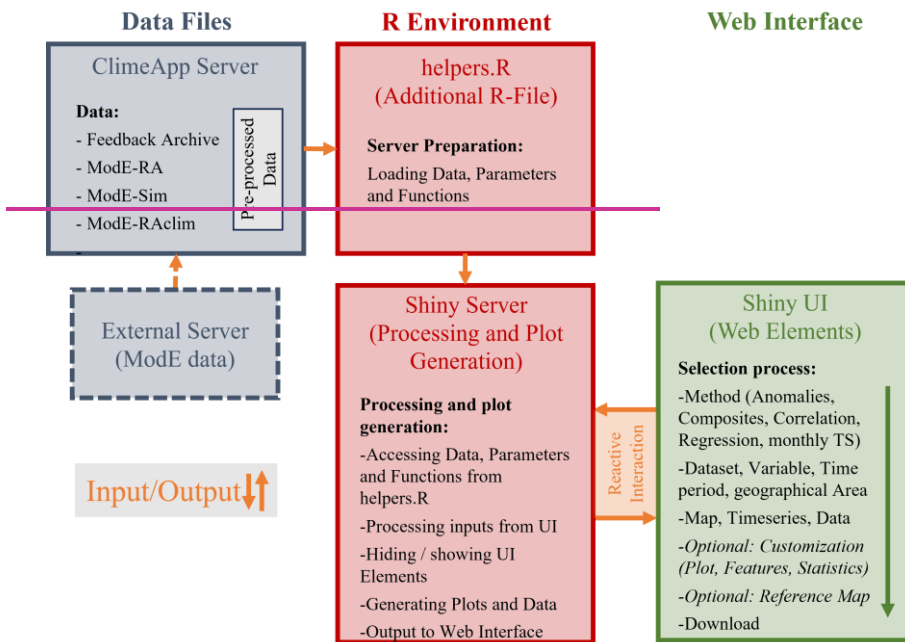

hat formatiert

hat formatiert

hat formatiert

Formatiert: Zentriert

145 **Figure 2.** Internal Structure of ClimeApp, showing how the data storage, R environment and web interface interact.

In ClimeApp, ModE data from an external server is stored locally on the ClimeApp server, including some pre-processed data to reduce loading times. All the server preparation, such as loading the R-libraries, unpacking the data, loading in parameters and predefined functions is done in a supporting R-file called `helpers.R`. The main `app.R` file consists of a `UI` section, where all the elements are defined, named and positioned, and a `Server` section where processing of inputs and plot generation is performed. When in use, the `Server` and web interface interact with each other reactively, with inputs from the web elements processed in real time and then output as plots or data tables. All web elements have preset inputs to generate an initial plot, which can then be altered by the user.

### 3.2 Usability

155 The ClimeApp web interface is designed to streamline data selection, providing all necessary information and options without being overly complex. The initial `Welcome` page displays general information about the ModE database and ClimeApp and gives access to five main tabs, one for each of the primary functions shown in Figure 1. We deliberately decided to supply only functions that are commonly used in historical climatology, but allow users to easily download selected ModE data for further processing. Input and customization options are selected within a tab, appearing on the same screen as the plots. For new users, it is vital not to overload the interface with information - be it with text or advanced options. To avoid this, we work with help texts that explain how plots and data are calculated, but only when selected. The interface is also streamlined by hiding many UI elements until they are required. Non-standard tools such as custom months, single year maps and additional features to customize plots are only visible when the relevant customization option or tick box is selected.

### 3.3 Customization

Having generated a plot, users have several options to customize their maps and timeseries. ClimeApp is designed to create graphics suitable for publication without the need for further editing in other programmes. The app supplies three sets of tools to customize plots: *Customize your map/timeseries*, *Custom features*, and *Custom statistics*. Under *Customize your plot*, the user can change titles, subtitles and the plot's axis. Once selected, axis values will stay fixed even after a plot has been changed, making it easy to quickly compare different regions and time periods. *Custom features* adds and removes points, lines and highlights to/from the plot and includes a location search function (Tennekes, 2021) that can add labelled, geocoded points. *Custom statistics* allows users to add the *SD ratio* or *% sign match* statistics (see Appendix 2 for more information) as overlays to their maps or add percentiles and moving averages to their timeseries. All customization stays, even when plots are altered or different variables selected, saving time when creating multiple plots. Customization and plot inputs can also be downloaded, saved and re-uploaded to quickly recreate previous plots.

### 3.4 Uploading/downloading data and plots

Nearly all the plots in ClimeApp can be downloaded in multiple file formats. Plot data can also be exported for use in other programmes. In the *Anomalies* tab, advanced users can download multiple ModE variables as a single NetCDF file, while in the *Regression* tab, a statistical summary of the linear regression is also available for download. Users can upload their own data in three of the main tabs: *Composites* can be created from an imported set of years, while tables of annual data can be uploaded for *Correlation* or *Regression* analysis. Uploaded files can be compared with either ModE variables or further user data, making ClimeApp a useful tool for performing simple correlation and regression analysis on your own material. Since files must be correctly formatted for ClimeApp to understand them, when uploading, users are shown an example image demonstrating how to correctly structure their file.

### 3.5 Reactive functions and pre-processing

One major benefit of Shiny apps is instant updating – as soon as a user selects new values, ClimeApp will automatically update its plots to match the new selection. This is timesaving and allows researchers to explore the climate data quickly and efficiently. Exceptions have been made for changing the geographical area, adding points, lines and highlights and using *Annual Cycles* function, to allow all information to be entered before updating the plot. To enable plots to instantly update, ClimeApp uses R Shiny's *reactive functions*. These functions track all the variables they depend on, re-executing if one of these variables changes. This means that only sections of code where a change has been made are re-run, reducing processing power and increasing response time. Reactive functions chain - each passing an output to a further reactive function until the final reactive output is passed to the UI, updating the onscreen plot or table.

To further reduce processing time, ClimeApp employs pre-processed data for common user selections. These include five seasonal averages: December-January-February (DJF); March-April-May (MAM); June-July-August (JJA); September-October-November (SON); and Annual; and ~~three-four~~ variables: Temperature; precipitation; ~~and~~ sea level pressure; ~~and~~ 500 hPa geopotential height. Annual means for each are already calculated and stored on the ClimeApp server, allowing them to be plotted without further computation. This considerably reduces the memory and time required for data processing and is especially valuable when users are working on large geographical areas or over long time periods.

## 4 Case Study – Tambora reanalysed

In 1815, on the Indonesian island of Sumbawa, Mount Tambora erupted. Large volumes of sulphur were injected into the stratosphere, forming a layer of aerosols around the globe. This layer considerably reduced incoming solar radiation, significantly affecting the global and particularly European climate (Brönnimann and Krämer, 2016). Using the latest and most comprehensive climate data, ModE-RA, ModE-Sim and ModE-RAclim, and the tools in ClimeApp, we can take a new look at the eruption's impact.

#### 4.1 Tambora in ModE-RA, ModE-Sim and ModE-RAclim

The year of 1816, following Tambora, has become known as the 'year without a summer', due to the extreme global temperature anomalies that followed the eruption. Using ClimeApp's *Anomalies* function, we can see the unusually cold summer temperatures over Europe in all three ModE datasets:

hat formatiert: Französisch (Schweiz)

hat formatiert: Schriftart: Kursiv

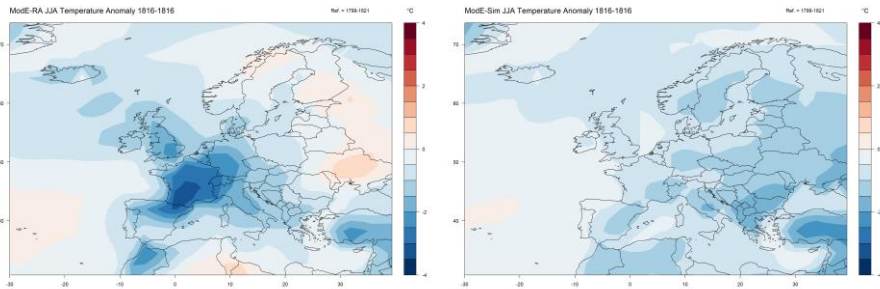

Formatiert: Zentriert

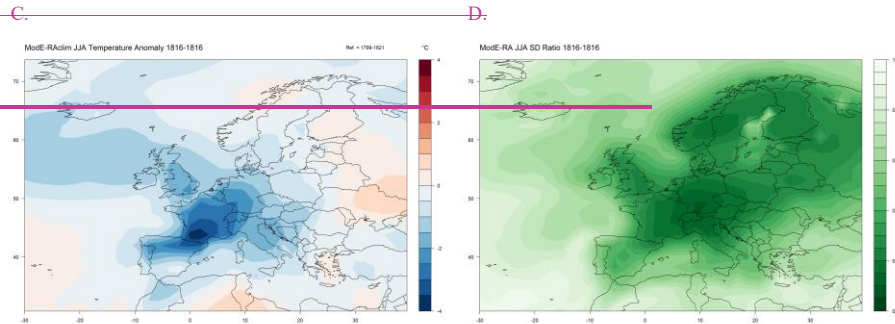

225

A.

B.

230 **Figure 4.** (a)A, (b)B & (c)C European temperature anomalies for June, July and August, 1816, as compared to reference period 1799 to 1821. Showing results from ModE-RA, ModE-Sim and ModE-RAclim, respectively. (d)D The standard deviation ratio (or SD ratio) between the ensembles of ModE-RA and ModE-Sim (see Source Analysis and Further Statistical Functions in Appendix 2 for more information).

235 A comparison between the datasets shows that the 1816 anomalies in ModE-RA and ModE-RAclim are essentially the same, while ModE-Sim reports considerably smaller temperature changes. This suggests that either certain mechanics of the Tambora eruption are not captured by the ModE-Sim ensemble, or that only part of the observed cooling can be explained by aerosol forcing. The latter might indicate that lower temperatures were partly due to internal climate variability. This would support the suggestion by Auchmann et al. (2013) and Brönnimann and Krämer (2016) that additional cooling in the 1810s may have been attributable to the long-term effects of the 1809 'unknown eruption', low solar activity and internal decadal variability in the ocean-atmosphere system.

245 The similarity between ModE-RA and ModE-RAclim results from the profusion of data sources for this period and region - 4778 European observations were assimilated for April to September in 1816 alone (see Figure 6). These constrain ModE-RA and ModE-RAclim, but not ModE-Sim. We can see this from the SD ratios in Figure 4d. The SD ratio measures the difference in spread between the ensembles of ModE-RA and ModE-Sim. An SD ratio of 1 means that both ensembles have the same standard deviation, i.e. nothing was assimilated or observations had no effect, while an SD ratio of 0 indicates an overconfident reanalysis since no uncertainty would remain. In general however, a lower SD ratio indicates where more information has been assimilated. In 250 4d, we can see this over central and northern Europe, where the lower SD ratio suggests a more reliable reanalysis, or at least one that is closer to the observations.

However, the SD ratio should not be the only measure of the dataset's reliability. If we use ClimeApp to view global precipitation rather than temperature in 1816, we can see the disparity between the ModE datasets reverse:

hat formatiert: Schriftart: Nicht Fett

hat formatiert

hat formatiert

hat formatiert

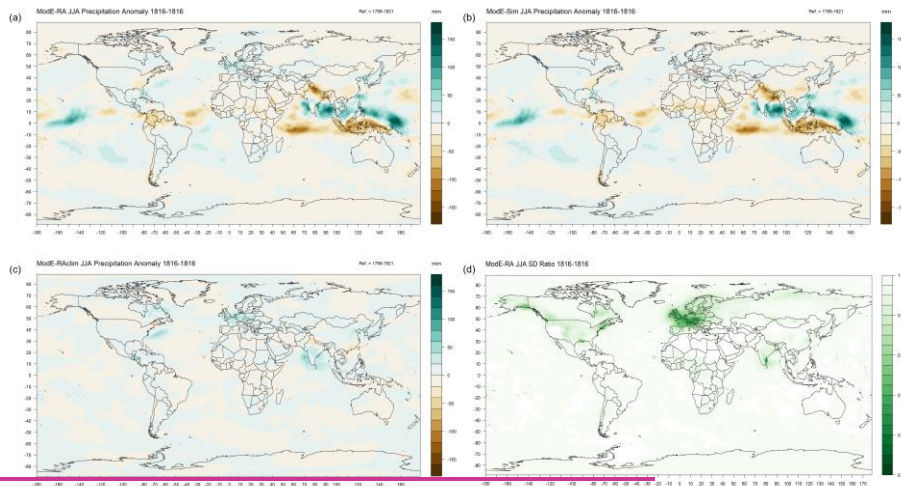

hat formatiert

hat formatiert

hat formatiert

hat formatiert

255

A. ————— B.

C. ————— D.

260 **Figure 5.** (a)A, (b)B & (c)C Global precipitation anomalies for June, July and August 1816, as compared to reference period 1799 to 1821. Showing results from ModE-RA, ModE-Sim and ModE-RAclim respectively. (d)D Standard deviation (SD) ratio of ModE-RA ensemble to ModE-Sim ensemble, showing significant constraint by observations only over Europe, coastal North America and SE India.

265 Here, ModE-RA very closely matches ModE-Sim, but not ModE-RAclim. This is because, while the tropical monsoon should have been seriously affected by Tambora (Marti and Ernst, 2009), there are few equatorial observations to capture this. ModE-RAclim is therefore unable to reconstruct significant changes in tropical precipitation. ModE-Sim meanwhile, includes physical mechanisms predicting extreme monsoon changes from volcanic aerosol forcing, and passes these on to ModE-RA. Interestingly, in the one tropical location that is more constrained - southern India (see Figure 5a-D) - ModE-RAclim does more closely match the predictions from

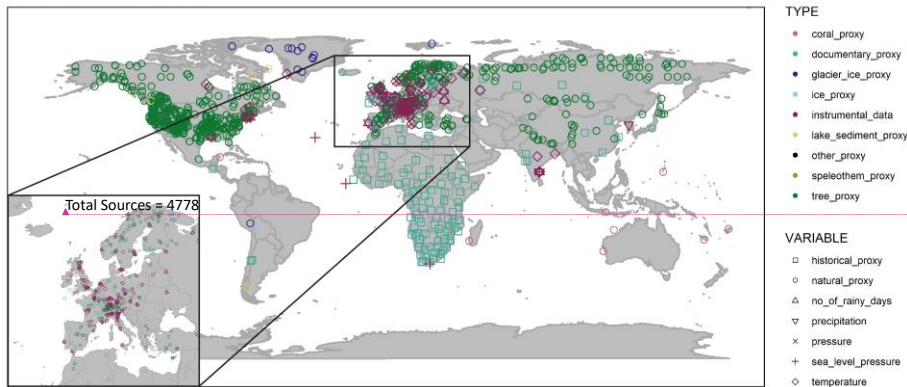

Formatiert: Zentriert

hat formatiert

270 ModE-Sim. Results from both precipitation and temperature broadly agree with previous reconstructions (Brönnimann, 2015) and modelling (Wegmann et al., 2014), though there are some regional differences in precipitation which might reflect improved modelling or more comprehensive observations.

### Assimilated Observations - Apr. to Sept. 1816

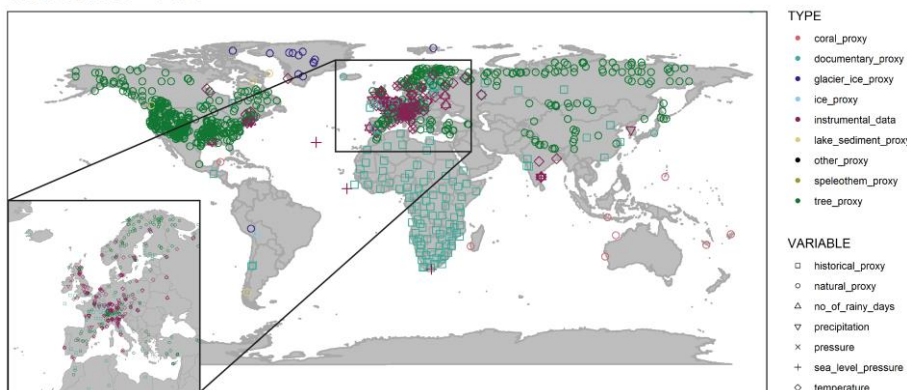

Total Sources = 7470

hat formatiert: Schriftart: (Standard) +Textkörper (Calibri), 8 Pt.

### Assimilated Observations - Apr. to Sept. 1816

Total Sources = 7470

275 **Figure 6.** ClimeApp *ModE-RA sources* plot, showing all assimilated observations for April to September 1816. By comparing the sources plot to the SD ratios (Figures 4d-D and 5d-D), we can see which observations significantly constrain the ModE-RA ensemble for a particular variable. For example, instrumental data (red) noticeably constrains JJA temperatures in Europe (Figure 4d-D), but the documentary proxies (yellow) in Africa have only a minor effect on the ensemble (possibly because the proxies correlate only weakly with boreal summer temperatures).

hat formatiert: Schriftart: Nicht Fett

hat formatiert: Schriftart: Nicht Fett, Kursiv

hat formatiert: Schriftart: Nicht Fett

hat formatiert: Schriftart: Nicht Fett

#### 4.2 Compositing volcanic years

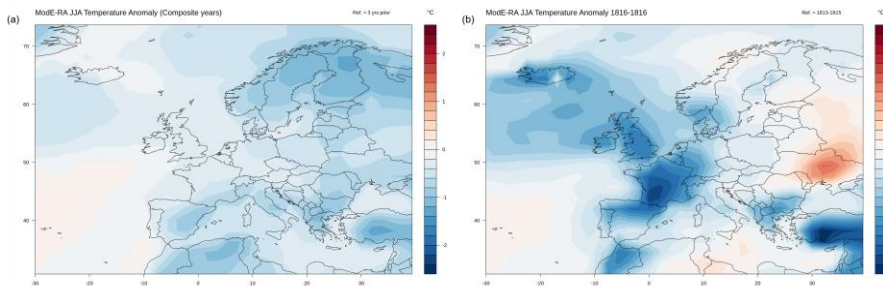

280 To compare Tambora with other volcanic eruptions, we can use the *Composites* function in ClimeApp to view the temperature anomalies in 1816 alongside a composite of the anomalies following other major eruptions:

hat formatiert

hat formatiert: Schriftart: Kursiv

hat formatiert

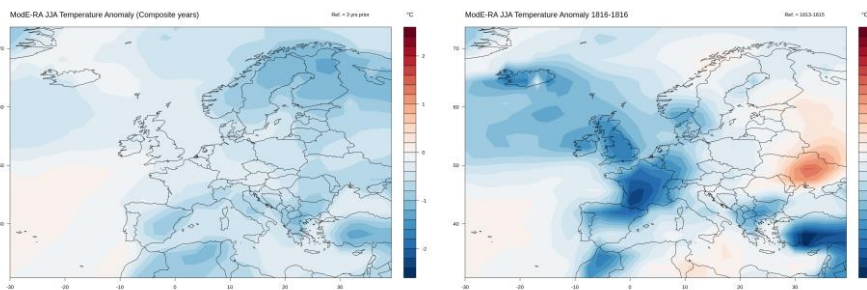

Formatiert: Zentriert

285

A. B.

290

**Figure 7.** (a) Composite of JJA temperature anomalies following the 12 largest volcanic eruptions, excluding Tambora, between 1422 and 2008, as measured by their impact on global stratospheric aerosol optical depth (Toohey and Sigl, 2017). Compositing years are 1454, 1459, 1596, 1601, 1642, 1696, 1784, 1810, 1832, 1836, 1884 and 1992, corresponding to the maximum volcanic forcing following each eruption. Anomalies are calculated with respect to the three years preceding each composite year. (b) Temperature anomalies in 1816, following Tambora, as compared to the three years prior.

hat formatiert: Schriftart: Nicht Fett

In the ModE-RA dataset, we see considerably larger anomalies following Tambora than in the more general composite of other eruptions. While this could suggest other, non-volcanic effects on the European climate, it is likely that the more individual patterns of each eruption are smoothed out in the composite, generating the more homogeneous weaker cooling. In this case, compositing highlights the forced part of the volcanic signal, similar to running an ensemble of simulations. This would explain the similarity between Figure 7a and Figure 4b (the ensemble mean from ModE-Sim). The disparity may also partly result from the volcanic forcing following Tambora being approximately twice that of the composite sample or the fact that the composite volcanic years were also generally less constrained than 1816 and therefore closer to ModE-Sim.

hat formatiert: cf01

### 300 4.3 Removing the volcanic signal?

Using ClimeApp, we can also attempt to remove the volcanic signal altogether from ModE-RA. The volcanic forcing data used in ModE-Sim (Toohey and Sigl, 2017), measures global volcanic forcing through reconstructed stratospheric aerosol optical depth (SAOD). ClimeApp's linear Regression function can build a simple statistical model linking SAOD to European JJA temperatures. In principle this can 'remove' associated effects (at least according to the linear regression model), leaving the 'residual' temperature variation unrelated to volcanic forcing (Fig. 8c):

315 **Figure 8.** (a) Timeseries showing the 'original' European JJA temperatures (1422-2008) used to train the model and the predicted trend in temperatures from predicted by the regression model. Note that both timeseries show the spatial average for each year, while the actual regression model consists of an original and trend for each point on the map. (b) Map showing the linear regression coefficients linking JJA temperature and global SAOD. (c) Residual European JJA temperatures in 1816.

320 The residuals (Fig. 8c) show significant non-volcanic anomalies in 1816, that generally match the results from the anomaly and composite analysis. The regression coefficients (Fig. 8b) agree with the results from ModE-Sim, predicting a mostly homogenous cooling over the European landmass in response to aerosol forcing. However, any further conclusions are limited by the assumption of a linear relation between SAOD and JJA temperatures. This is unlikely, given the complex atmospheric dynamics governing the climate response to the radiative forcing (Brönnimann, 2015). Furthermore, the limited number of major eruptions reduces the reliability of any relationship drawn from a simple comparison of the data.

325

#### 4.4 Comparing ModE-RA to historical data

330 Tambora didn't only affect the climate, human society was also significantly impacted. At the turn of the 19<sup>th</sup> century, grain prices were the most important indicator to measure the state of an economy (Ljungqvist et al., 2022). Even if other factors such as demand, military conflicts and the quality of the harvest played a role, quantitative supply was an important determinant of price (Krämer, 2015). We would therefore expect a link between price data and temperatures during the growing season. This can be tested using a sample of bread price data from Lucerne, Switzerland and ClimeApp's *Correlation* function:

- hat formatiert: Schriftart: Nicht Fett
- hat formatiert: Nicht Hervorheben
- hat formatiert: Schriftart: Nicht Fett
- hat formatiert: Nicht Hervorheben
- hat formatiert: Schriftart: Fett

- hat formatiert
- hat formatiert: Hochgestellt
- hat formatiert

- hat formatiert: Schriftart: Kursiv
- hat formatiert

335 **Figure 9.** Timeseries correlation showing JJA temperatures from 1750-1850 over central Europe and the average price of bread (“Weissbrot”) in Lucerne, Switzerland for the following year (Haas-Zumbühl, 1903). Timeseries correlation of  $r = -0.328$ , with a  $p$  value  $< 0.01$ . Prices are in Rappen per kg. Note that the following year bread price was used due to the “[lagged effect](#)” of [between market price and temperature during the growing season on market prices](#).

hat formatiert: Schriftart: Nicht Fett

340 The timeseries correlation gives us an inverse correlation of  $r = -0.328$ . This implies a weak but general correlation between the growing season temperatures and grain prices, where low temperatures presumably led to a poor season and a spike in bread prices [the following year](#). The connection is particularly visible after Tambora, where we see both a sharp rise in prices (in 1817) and a sudden temperature drop during the summer season of 1816. This coincided with unusually high precipitation, which may explain why we do not see a similar price spike in 1813 or 1821 [when precipitation was moderate](#). Our results agree with previous work on Tambora, which demonstrated how adverse weather in Switzerland in 1816 played a crucial role in massively reduced crop yields. In the following year, this led to an increase in prices for grain and bread and widespread famine, particularly in eastern Switzerland (Brönnimann and Krämer, 2016).

hat formatiert

## 5 Outlook

### 5.1 Potential for humanities

350 It is well known how intertwined climate and society have been over the last 1000 years (Pfister and Wanner, 2021). Naturally, this has important implications for all sciences that concern themselves with humanity, but

hat formatiert

especially for history. An understanding of the climate can complement traditional historical approaches, adding a crucial dimension to our understanding of the past. As ~~demonstrated we did~~ in our case study ~~for the summer of 1816~~, anomaly plots for specific years

hat formatiert

hat formatiert

can illustrate how different regions were affected by extreme climate events. Correlations can ~~depict the measure statistical connections~~ between ~~historical and climate and historical~~ variables, ~~ranging from crop yields and mortality rates to price data~~ thus substantiating historic argumentation. Such ~~historical variables can range from crop yields and mortality rates to price data, as shown in the case study~~. Knowledge of climate history can also give us perspective on the current climate crisis, ~~with historical examples employed as case studies for the impacts of a changing climate on human societies~~ (Lamb, 2002; Degroot et al., 2021). However, there are still challenges to interweaving the two disciplines. These include the heterogeneity of approaches, the diversity of disciplinary perspectives and often mutually unintelligible terminology (White et al., 2023). We can innovate to overcome these difficulties though however. ~~To this end, T~~here exists a growing collection of databases and tools for accessing documentary sources and climate data for use in ~~on~~ historical climatology. Some primary ~~e~~xamples include ~~tambora.org~~ (Riemann et al., 2015), ~~and Euro-Climhist~~ (Pfister et al., 2017) ~~https://www.euroclimhist.unibe.ch/en/~~ and ~~Climate Explorer~~ (Trouet and van Oldenborgh, 2013). ~~— and these are now used in both historical and climatological research.~~

hat formatiert

hat formatiert

hat formatiert

hat formatiert

hat formatiert

hat formatiert

hat formatiert

hat formatiert

hat formatiert

hat formatiert

Each tool fulfils a different niche ~~has its own array of functionality for different research purposes~~. ~~Tambora.org and Euro-Climhist both provide a vast number amount of original sources and indexed data information from (predominantly) human archives. This qualitative data with exact references to their individual sources - usually documentary data, but in the case of Euro-Climhist also visual sources such as paintings — is extremely helpful forean be used to look at investigating and interpreting singular events or climatological trends. However, it is often sporadic and temporally and geographically inhomogeneous, hence the advantage of modelling and reanalysis products like ModE-RA and ModE-Sim. Climate Explorer meanwhile, is an excellent tool for accessing and analysing some older climate reconstructions, as well as modern instrumental data. However, its vast array of options and data can often be confusing for new users, and it does not give access to the very latest reanalysis data.~~

hat formatiert

hat formatiert

hat formatiert

hat formatiert

This is where ClimeApp is able to provide a complimentary tool, utilizing a smaller range of data and functions, but via a far more user-friendly interface. ~~Unlike Climate Explorer~~, ClimeApp provides highly customizable plots, along with helpful explanations where necessary. It also, uniquely, allows users to view all the sources behind the reanalysis data. Combined with the standard deviation ratios (see case study, section 4.1), these allow detailed assessment of the reliability and applicability of the reanalysis. For historians, this possibility to make ~~source-attributed, publication suitable plots without coding skills is invaluable. Furthermore, for researchers~~ ~~historians~~ using quantitative data, ClimeApp can be a convenient tool for correlation or regression analysis without needing external programmes. However, the most important feature of ClimeApp is that it ~~and ClimeApp use both reanalysis data to reconstruct the global past climate. ClimeApp stands out with its simple and neat user interface, its highly customizable plots and the fact that is uses the most extensive and most modern global reanalysis data for the global climate of the last 600 years, which can be directly compared with historical socio-economic time series. In general,~~

hat formatiert

hat formatiert

hat formatiert

hat formatiert

395 However, there are still challenges to interweaving the two disciplines. These include the heterogeneity of  
approaches, the diversity of disciplinary perspectives and often mutually unintelligible terminology (White et al.,  
2023). We can innovate to overcome these difficulties however. ClimeApp provides a tool for accessing state-of-  
the-art data on the past global climate and the possibility to easily plot climate variables without coding skills.  
Source maps and standard deviation ratios provide simple and hopefully easily understandable tools to assess the  
reliability and relevance of the data. Furthermore, for historians using quantitative data, ClimeApp can be a  
400 convenient tool for correlation or regression analysis without needing external programmes. The broad appeal  
of ClimeApp for the humanities to use ClimeApp lies in its simplification of accessing, visualising and  
analysing the latest reanalysis data, of scientific analysis, breaking it down, guiding the users through all the  
important steps and providing explanations where needed.

## 5.2 Potential for climate sciences

405 We have already demonstrated some of ClimeApp's potential for climate science in our case study, but a few  
further points are worth making here. First and foremost, ClimeApp can save researchers considerable time  
creating field and timeseries plots that would otherwise have to be manually coded. As it incorporates many  
analysis methods used in historical climatology and paleoclimatology, climatologists studying the age before  
instrumental measurements will find the ModE data invaluable. Our case study showed how contrasting ModE-  
410 RA, ModE-Sim and ModE-RAclim can give constructive insights into the causes of certain climate anomalies,  
while the source plots and SD ratio data can be used to assess the reliability and the limitations of ModE data.  
For the developers of ModE-RA, ClimeApp is particularly useful for testing their data, allowing them to quickly  
visualise and compare the datasets. Other researchers can use the app to assess new paleoclimate data, using the  
Correlation function to map correlations between their data and ModE-RA. For students and lecturers, we hope  
415 that ClimeApp makes advanced reanalysis data easily accessible for exercises and project work. Finally,  
ClimeApp can be a useful template for developing other Shiny projects, particularly those for processing and  
plotting complex data. The source code for the application is openly available (see Code availability) and can be  
freely adapted for other applications.

## 6 Conclusions

420 This paper summarized the functionality and potential of the new ClimeApp web application. It demonstrates  
how simple applications can be powerful tools to make specialized data available to all. The application provides  
historians, climatologists and other researchers quick access to state-of-the-art ModE climate reanalysis.  
Through a user-friendly interface, students and scientists can view and analyse the historical global climate with  
just a few clicks. Furthermore, and uniquely, ClimeApp allows detailed investigation of the sources used in a  
425 climate reconstruction. The ModE-RA sources tool displays the type and location of all proxies and  
documentary sources used to constrain the ModE-RA climate models, while the SD ratio statistical analysis  
quantifies their effect on the final data. By re-examining the Tambora eruption and the 'year without a summer'  
in 1816, we demonstrated how combining results from ModE-RA, ModE-Sim and ModE-RAclim can help us  
interpret the reanalysis data and begin to separate different factors affecting the paleoclimate. We also showed  
430 how the correlation and regression functions can be used to combine ModE-RA with independent data to identify

statistical relationships between climatic and non-climatic variables. ClimeApp, created and developed by a historian, geographers and a climate scientist, is as good an example as any of the value of bridging science and humanities to advance interdisciplinary research. In this paper we have focussed on the app's potential in our respective fields, but possible applications could be imagined in many of the social and physical sciences. Our hope is that researchers from various disciplines will benefit from using ClimeApp and ModE-RA, finding innovative and enlightening ways to integrate climate data into their own research.

## 7 Appendices

### Appendix 1: R libraries used by ClimeApp

library(shiny)

library(ncdf4)

library(maps)

library(shinyWidgets)

library(RColorBrewer)

library(shinyjs)

library(bslib)

library(readxl)

library(xlsx)

library(DT)

library(zoo)

library(colourpicker)

library(tmertools)

library(ggplot2)

library(sf)

library(shinylogs)

library(shinycssloaders)

ClimeApp v1.0 uses R-version 4.3.2.

### Appendix 2: ClimeApp functions and data processing

Behind the Shiny interface, the processing and analysis done by ClimeApp is relatively straightforward.

ClimeApp utilises the set of R libraries in Appendix 1 to extract and process the raw ModE data into a format selected by the user.

#### Anomalies

The anomaly map function shows the spatial distribution of climate anomalies averaged over a user-selected year range and month range. For example, June, July, August (JJA), 1501 to 1600 if your focus is boreal summer in the 16<sup>th</sup> century. The anomalies are created from 3 data products:

1. Annual Means – a timeseries of annual means for each point on the map, created by averaging absolute ModE values across the selected month range.

470 2. Reference Means – a single reference mean for each point on the map, created by averaging  
annual means across a chosen reference year range.

475 3. Annual Anomalies – a timeseries of annual anomalies for each point on the map, created by  
subtracting the reference means from the annual means.

The final anomalies shown are the time-averaged annual anomalies. These are plotted using the base R plotting functions along with the coastlines and borders from the *maps* package. The anomaly timeseries is generated by averaging the annual anomalies for each year.

475 For reference, the calculations behind each data product are as follows:

The annual mean for a single year and single point on the map is given by the equation

$$AnnualMean = \overline{AbsoluteValues(M)}$$

480 where *M* is the selected month range.

The reference mean for a single year and point is given by

$$ReferenceMean = \overline{AnnualMeans(Y_{ref})}$$

485 where *Y<sub>ref</sub>* is the selected reference year range.

The annual anomaly for a single year and point is given by:

$$AnnualAnomaly = AnnualMean - ReferenceMean$$

490 Note that in the case of ModE-RAclim, the base data is already in anomaly format, so anomalies are merely calculated by subtracting time-averaged anomalies from each other.

The anomalies presented on the anomaly map and in the anomaly map data are given by

$$Anomaly(map) = \overline{AnnualMeans(Y)} - ReferenceMean = \overline{AnnualAnomalies(Y)}$$

495 where *Y* is the selected year range.

Anomalies presented on the timeseries map and timeseries data are given by

$$\begin{aligned} Anomaly(timeseries) &= \overline{AnnualMeans(Lon, Lat)} - \overline{ReferenceMeans(Lon, Lat)} \\ &= \overline{AnnualAnomalies(Lon, Lat)} \end{aligned}$$

500 where *Lon* and *Lat* are the selected longitude and latitude range.

### 500 **Composites**

ClimeApp's composite maps show the time-averaged anomalies for a set of non-consecutive years, which can be entered or uploaded by the user. The anomaly reference period can be a fixed set of consecutive years, a custom set of non-consecutive years or an individual reference period generated for each year based on the *X* (a number of years chosen by the user) years prior. Calculations and plotting are performed in the same way as for anomalies, except for anomalies compared to *X* years prior (XYP):

505

1. XYP Reference Means – a set of reference means for each point on the map, one for each user-selected year. Calculated by averaging the  $X$  preceding *annual means*.
2. XYP Annual Anomalies – a set of annual anomalies for each point on the map. Created by subtracting the corresponding *reference mean* from each *annual mean*.

To give an indication of the consistency of anomalies over the set of years in the composite, ClimeApp contains a ‘% sign match’ statistical tool. This marks regions where the *annual anomalies* that form the composite agree in their sign more often than a user-defined threshold, given in percent. For example, for a composite of five years, with anomalies of -1°C, -5°C, 1°C, 15°C and -3°C, the displayed mean would be a positive 1.4°C, but only 40% of the years would match this, since 3 are in fact negative.

### **Correlation**

The correlation function allows users to generate a map of correlation coefficients, comparing either ModE variables or user-uploaded timeseries. Using the *cor()* function from the *stats* R package (R Core Team, 2022), it can employ either the Pearson or Spearman’s Ranks correlation method. If both variables are in ‘field’ format, i.e. gridded map data, it performs a timeseries correlation of the *annual means* for each point on the map with the corresponding *annual means* for the second variable. If one variable is a timeseries however, it correlates each set of *annual means* with the same timeseries. In addition to the map, ClimeApp also produces a correlation timeseries, showing an annual timeseries of both variables (spatially averaged in the case of ModE variables) and a single correlation coefficient and p-value, calculated from those timeseries. The p-value shows the probability that the correlation was produced by random chance rather than an actual relationship between the variables.  $p < 0.05$  is generally recommended for drawing legitimate conclusions.

### **Regression**

In ClimeApp, regression operates in a similar way to correlation, performing a multiple linear regression analysis on a set of *annual means*. Using *lm()* from the *stats* R package, one or more independent variable timeseries are fitted to the dependent variable timeseries for each point on the map according to the model

$$V_{\text{dependent}} = \beta_1 V_{\text{independent}_1} + \beta_2 V_{\text{independent}_2} + \dots + \alpha + \text{Residual}$$

where  $\beta$  is the coefficient and  $\alpha$  is the intercept. ClimeApp then plots the spatial average of the dependent variable, trend ( $\beta_1 V_{\text{independent}_1} + \beta_2 V_{\text{independent}_2} + \dots$ ) and residual as a timeseries. Provided the dependent variable is a field, maps of the coefficients for each independent variable can be produced, as can maps of the p-values and residuals for each year.

### **Annual Cycles**

This function shows the spatially averaged monthly ModE values over a given year or set of years. In the case of a set of years, these can be presented individually or as an average.

### **Source Analysis and Further Statistical Functions**

The accuracy of ModE-RA is dependent on the availability and reliability of observations to constrain the model ensemble of ModE-Sim. To capture this, ClimeApp includes tools for visualizing the sources

used to create ModE-RA and ModE-RAclim and the standard deviation (SD) ratio of the ModE-RA and ModE-Sim ensembles. The ModE-RA sources are presented as a semi-annual map showing the data points assimilated for each half-year, grouped by type and variable (see Figure 6). This allows the user to see where proxy, documentary or instrumental observations were integrated into the reconstruction and any gaps in the data. The SD ratio meanwhile, is the standard deviation of the ModE-Sim ensemble divided by the standard deviation of ModE-RA after the assimilation of observations:

$$SDratio = \frac{\sigma_{ModE-RAEnsemble}}{\sigma_{ModE-Ensemble}}$$

This gives a value between 0 and 1 for each month and grid point, with 1 showing no constraint (i.e. the ModE-RA output is the same as that of ModE-Sim and entirely generated from the models) and lower values showing increasing constraint by observations, meaning there are either more observations or that they are more 'trusted' by the reconstruction. The temporal mean of the SD ratio can be presented in ClimeApp as a contour map or grid-point overlay on the anomaly maps.

On timeseries plots, users have the option to add percentiles and moving averages. The moving averages are calculated using a rolling mean of timeseries values over a number of years selected by the user (default 11). To generate the percentiles, a Shapiro-Wilk test (Shapiro and Wilk, 1965) is first conducted on the timeseries data. If the data is normally distributed, which is rare for ModE timeseries, then percentiles are calculated from the mean and standard deviation of the timeseries using the *qnorm()* function from the *stats* package. If the distribution is non-normal, ClimeApp instead finds the value corresponding to the quantile matching the users selection (i.e. for the 0.95 percentile, it returns values that 5% of all values are above/below), using the *quantile()* function from the *stats* package.

### Appendix 3: Current limitations and future development

The data available in ClimeApp is currently limited to ModE-RA, ModE-Sim and ModE-RAclim, and only four variables within those datasets. There are limited options for users to upload and process other data, but the format of this data is currently restricted to annual time series. The web app's ability to host a large number of users at the same time is also constrained by current processing power. To address some of these issues and to add further functionality to ClimeApp, a four stage development plan has been devised:

- |                          |   |
|--------------------------|---|
| <u>1. Facilitation</u>   | <ul style="list-style-type: none"> <li>• Interactive map to look at ModE-RA sources as an access point for the ModE-RA feedback archive, a database detailing each used source</li> <li>• Several video tutorials to facilitate the use of ClimeApp</li> <li>• Obtain funding and increase available processing power to reduce loading times and facilitate multiple simultaneous users</li> </ul> |
| <u>2. Optimization</u>   | <ul style="list-style-type: none"> <li>• Optimized and stream-lined plotting (e.g. various projections for global maps, pacific centred plotting)</li> <li>• More options for customization (e.g. for regression and correlation)</li> <li>• Ability to export georeferenced raster and vector files for usage in GIS</li> </ul>  |
| <u>3. Implementation</u> | <ul style="list-style-type: none"> <li>• Access to individual ModE-Sim ensemble members for more detailed study</li> <li>• Access to more variables from ModE-RA, such as wind speed and direction</li> </ul>   |

- Possibility for users to upload their own georeferenced data for purposes of plotting, averaging and correlation/regression against the ModE-RA data

#### 4. Cooperation

- API for other web-based research environments such as nodegoat (van Bree and Kessels, 2013)

#### **Appendix 4: Experience documentation, outreach and feedback**

575 ClimeApp underwent extensive internal and external testing before being deployed for general use. The beta version was introduced during a summer school in summer 2023 (Huhtamaa and Hibberts, 2024) and later  
580 trialled at several workshops and conferences, with both historians and climatologists. The initial user interactions and resulting valuable feedback included (but was not limited to): The addition of help texts to explain the different functions and options; the implementation of an interactive map of all ModE-RA sources to allow detailed source evaluation; faster data processing; more options for composite analysis; the addition of reference maps to see the reference and absolute values for anomalies; customization options for plots; and facility for multiple simultaneous users. This feedback was documented and either implemented or road mapped for future development (see Appendix 3).

585 The current version of ClimeApp has already been included in the curriculum of two courses at the University of Bern: Brönnimann, 2023, Climatology III (Climate variability and change); and Huhtamaa, 2023, Climate and Society in History. It will also be included in further courses at the University of Bern from 2024 onwards including a three session workshop introducing ClimeApp and its applications.

The full application was launched in early 2024 and presented at the EGU conference in Vienna and the Climate of the Past and Societal Responses to Environmental Changes conference in Bern.

590 ClimeApp has its own feedback and suggestion email address (climeapp.hist@unibe.ch), presented on the Welcome page, where users can report any issues and suggest improvements. These are then considered by the developers before being added to the application's Trello page (<https://trello.com/b/3hKu3RIL/climeapp-development>), where users to track their suggestions and see what we are currently working on. These contributions are vital for making ClimeApp as useful and user-friendly as possible.

615 ClimeApp v1.0 uses R-version 4.3.2:

## Appendix 2: ClimeApp functions and data processing

Behind the Shiny interface, the processing and analysis done by ClimeApp is relatively straightforward. ClimeApp utilises the set of R libraries in Appendix 1 to extract and process the raw ModE data into a format selected by the user.

### Anomalies

The anomaly map function shows the spatial distribution of climate anomalies averaged over a user-selected year range and month range. For example, June, July, August (JJA), 1501 to 1600 if your focus is boreal summer in the 16<sup>th</sup> century. The anomalies are created from 3 data products:

1. *Annual Means* — a timeseries of annual means for each point on the map, created by averaging absolute ModE values across the selected month range.
2. *Reference Means* — a single reference mean for each point on the map, created by averaging annual means across a chosen reference year range.
3. *Annual Anomalies* — a timeseries of annual anomalies for each point on the map, created by subtracting the *reference means* from the *annual means*.

The final anomalies shown are the time-averaged annual anomalies. These are plotted using the base R plotting functions along with the coastlines and borders from the *maps* package. The anomaly timeseries is generated by averaging the annual anomalies for each year.

635 For reference, the calculations behind each data product are as follows:

The *annual mean* for a single year and single point on the map is given by the equation:

$$AnnualMean = \overline{AbsoluteValues(M)}$$

where  $M$  is the selected month range.

640 The *reference mean* for a single year and point is given by

$$ReferenceMean = \overline{AnnualMeans(Y_{ref})}$$

where  $Y_{ref}$  is the selected reference year range.

hat formatiert: Schriftart: Kursiv

hat formatiert: Schriftart: Kursiv

hat formatiert: Schriftart: Kursiv

645

The *annual anomaly* for a single year and point is given by:

$$AnnualAnomaly = AnnualMean - ReferenceMean$$

Note that in the case of ModE-RAclim, the base data is already in anomaly format, so anomalies are merely calculated by subtracting time-averaged anomalies from each other.

650

The anomalies presented on the anomaly map and in the anomaly map data are given by

$$Anomaly(map) = \overline{AnnualMeans(Y)} - ReferenceMean = \overline{AnnualAnomalies(Y)}$$

where  $Y$  is the selected year range.

hat formatiert: Schriftart:

hat formatiert: Schriftart:

655

Anomalies presented on the timeseries map and timeseries data are given by

$$\begin{aligned} Anomaly(timeseries) &= \overline{AnnualMeans(Lon, Lat)} - \overline{ReferenceMeans(Lon, Lat)} \\ &= \overline{AnnualAnomalies(Lon, Lat)} \end{aligned}$$

where  $Lon$  and  $Lat$  are the selected longitude and latitude range.

hat formatiert: Schriftart:

### Composites

660

ClimeApp's composite maps show the time-averaged anomalies for a set of non-consecutive years, which can be entered or uploaded by the user. The anomaly reference period can be a fixed set of consecutive years, a custom set of non-consecutive years or an individual reference period generated for each year based on the  $X$  (a number of years chosen by the user) years prior. Calculations and plotting are performed in the same way as for anomalies, except for anomalies compared to  $X$  years prior ( $XYP$ ):

665

1.  $XYP$  Reference Means—a set of reference means for each point on the map, one for each user-selected year. Calculated by averaging the  $X$  preceding *annual means*.
2.  $XYP$  Annual Anomalies—a set of annual anomalies for each point on the map. Created by subtracting the corresponding *reference mean* from each *annual mean*.

hat formatiert: Schriftart: Kursiv

hat formatiert: Schriftart: Kursiv

670

To give an indication of the consistency of anomalies over the set of years in the composite, ClimeApp contains a '% sign match' statistical tool. This marks regions where the *annual anomalies* that form the composite agree in their sign more often than a user-defined threshold, given in percent. For example, for a composite of five years, with anomalies of  $-1^{\circ}C$ ,  $-5^{\circ}C$ ,  $1^{\circ}C$ ,  $15^{\circ}C$  and  $-3^{\circ}C$ , the displayed mean would be a positive  $1.4^{\circ}C$ , but only 40% of the years would match this, since 3 are in fact negative.

675

### Correlation

680

The correlation function allows users to generate a map of correlation coefficients, comparing either ModE variables or user-uploaded timeseries. Using the *cor()* function from the *stats* R package (R-Core Team, 2022), it can employ either the Pearson or Spearman's Ranks correlation method. If both variables are in 'field' format, i.e. gridded map data, it performs a timeseries correlation of the *annual means* for each point on the map with the corresponding *annual means* for the second variable. If one variable is a timeseries however, it correlates each set of *annual means* with the same timeseries. In addition to the map, ClimeApp also produces a correlation timeseries, showing an annual timeseries of both variables (spatially averaged in the case of ModE variables) and a single correlation coefficient and

685 p-value, calculated from those timeseries. The p-value shows the probability that the correlation was produced by random chance rather than an actual relationship between the variables.  $p < 0.05$  is generally recommended for drawing legitimate conclusions.—

### Regression

690 In ClimeApp, regression operates in a similar way to correlation, performing a multiple linear regression analysis on a set of *annual means*. Using *lm()* from the *stats* R package, one or more independent variable timeseries are fitted to the dependent variable timeseries for each point on the map according to the model

$$V_{dependent} = \beta_1 V_{independent_1} + \beta_2 V_{independent_2} + \dots + \alpha + Residual$$

695 where  $\beta$  is the coefficient and  $\alpha$  is the intercept. ClimeApp then plots the spatial average of the dependent variable, trend ( $\beta_1 V_{independent_1} + \beta_2 V_{independent_2} + \dots$ ) and residual as a timeseries. Provided the dependent variable is a field, maps of the coefficients for each independent variable can be produced, as can maps of the p-values and residuals for each year.

### Annual Cycles

This function shows the spatially averaged monthly ModE values over a given year or set of years. In the case of a set of years, these can be presented individually or as an average.

### 700 Source Analysis and Further Statistical Functions

The accuracy of ModE-RA is dependent on the availability and reliability of observations to constrain the model ensemble of ModE-Sim. To capture this, ClimeApp includes tools for visualizing the sources used to create ModE-RA and ModE-RAclim and the standard deviation (SD) ratio of the ModE-RA and ModE-Sim ensembles. The ModE-RA sources are presented as a semi-annual map showing the data points assimilated for each half-year, grouped by type and variable (see Figure 6). This allows the user to see where proxy, documentary or instrumental observations were integrated into the reconstruction and any gaps in the data. The SD ratio meanwhile, is the standard deviation of the ModE-Sim ensemble divided by the standard deviation of ModE-RA after the assimilation of observations:

$$SDratio = \frac{\sigma_{ModE-RAensemble}}{\sigma_{ModE-ensemble}}$$

710 This gives a value between 0 and 1 for each month and grid point, with 1 showing no constraint (i.e. the ModE-RA output is the same as that of ModE-Sim and entirely generated from the models) and lower values showing increasing constraint by observations, meaning there are either more observations or that they are more 'trusted' by the reconstruction. The temporal mean of the SD ratio can be presented in ClimeApp as a contour map or grid-point overlay on the anomaly maps.

715 On timeseries plots, users have the option to add percentiles and moving averages. The moving averages are calculated using a rolling mean of timeseries values over a number of years selected by the user (default 11). To generate the percentiles, a Shapiro-Wilk test (Shapiro and Wilk, 1965) is first conducted on the timeseries data. If the data is normally distributed, which is rare for ModE timeseries, then percentiles are calculated from the mean and standard deviation of the timeseries using the *qnorm()*

720

function from the *stats* package. If the distribution is non-normal, ClimeApp instead finds the value corresponding to the quantile matching the users selection (i.e. for the 0.95 percentile, it returns values that 5% of all values are above/below), using the *quantile()* function from the *stats* package.

### Appendix 3: Current limitations and future development

725 The data available in ClimeApp is currently limited to Mode-RA, Mode-Sim and Mode-RAclim, and only four variables within those datasets. There are It also has only limited options for users to upload and process other data, but the format of this data is currently restricted to annual time series. and t The web app's ability to host a large number of users at the same time is also limited/constrained by its current processing power. To address some of these issues and to add further functionality to ClimeApp, future development plans include:

- 730
- —
  - — Using the Mode-RA sources as an interactive access point for the Mode-RA feedback archive, a database detailing how each observation was used in assimilation process.
  - — Adding access to individual Mode-Sim ensemble members for more detailed study.
  - — Adding access to more variables from Mode-RA, such as wind speed and direction.
- 735
- — Allowing users to upload their own gridded field data for purposes of plotting, averaging and correlation/regression against the Mode-RA data.
  - — An API for other web-based research environments such as nodegoat (van Bree and Kessels, 2013).
  - — The export of georeferenced raster and vector files for usage in GIS.

### 740 Appendix 4: Outreach and feedback

and external before being deployed for general use in summer 2023 (Hibberts and Huhtamaa, 2024) and later trialled at several, with both historians and climatologists included (but was not limited to): The addition of help texts to explain the different functions and options; the implementation of an interactive map of all Mode-RA sources to allow detailed source evaluation; faster data processing; more options for composite analysis; the addition of reference maps to see the reference and absolute values for anomalies; customization options for plots; and facility for multiple simultaneous users. This feedback was documented and either implemented or road mapped for future development (see Appendix 3).

745

•

The current version of ClimeApp has already been included in the curriculum of two courses at the University of Bern: Brönnimann, 2023, Climatology III (Climate variability and change); and Huhtamaa, 2023, Climate and Society in History. It will also be included in further courses at the University of Bern from 2024 onwards including a three-session workshop introducing ClimeApp and its applications.

750

The full application was launched in early 2024 and presented at the EGU conference in Vienna and the Climate of the Past and Societal Responses to Environmental Changes conference in Bern.

ClimeApp has its own feedback and suggestion email address ([climeapp.hist@unibe.ch](mailto:climeapp.hist@unibe.ch)), presented on the *Welcome* page, where users can report any issues and suggest improvements. These are then considered by the

Formatiert: Überschrift 2

760 ~~developers before being added to the application's Trello page (<https://trello.com/b/3hKu3RIL/climeapp-development>), where users to track their suggestions and see what we are currently working on. These contributions are vital for making ClimeApp as useful and user friendly as possible.~~

#### **Code availability**

The essential code of ClimeApp – *app.R* and *helpers.R* – is available on the projects GitHub page.

#### **Author contributions**

770 NB and RW conceptualized, created and developed ClimeApp as part of their respective PhD projects. They conducted research and analysed data for the case study, produced all graphs and figures and contributed equally to the manuscript. NW co-developed ClimeApp, is responsible for the mail-feedback and manages the Trello page. JF and RH wrote the SD ratio function used in ClimeApp, set up the university server and gave technical advice on the ModE data and contributed to the writing of the manuscript. HH and SB encouraged and promoted the creation of the application and helped with the scientific outreach for the project. All authors discussed the project and its results, helped with the quality control of the final product and provided comments on the manuscript.

#### **Competing Interests**

The authors declare that they have no conflict of interest.

#### 780 **Disclaimer**

#### **Acknowledgements**

785 ~~Niklaus Bartlome, Richard Warren, Noémie Wellinger, Heli Huhtamaa (project PI) and Luc Billaud (graphics designer and creator of the logo) received funding from the State Secretariat for Education, Research and Innovation (SERI contract number MB22.00030, VolCope) and the Swiss National Science Foundation (SNSF grant number PZ00P1\_201953, DEBTS).~~

~~Jörg Franke, and Ralf Hand, and Stefan Brönnimann~~ received funding form the European Union H2020/ERC grant number 787574 PALAEO-RA. The ECHAM6 simulations (ModE-Sim) were performed at the Swiss Supercomputer Centre (CSCS) and the University of Bern Linux Cluster (UBeLix).

## Financial Support

ClimaApp is developed within the frame of the NB, RW, NW and HH were supported by VICES (Volcanic Impacts on Climate, Environment and Society) project, which is funded by SERI the Swiss State Secretariat for Education, Research and Innovation (contract number MB22.00030) and Swiss National Science Foundation SNSF (grant number PZ00P1\_201953). JF, RH and SB received funding from the European Union's Horizon 2020 (grant number 787574).

(Posit team, 2024)(R Core Team, 2022)ClimaApp relies heavily on the ModE-RA database. Its project PALAEO-RA is funded with H2020/ERC grant (grant number 787574).(Chang et al., 2024)(Tennekes, 2021)
