Geological sketch map of the Popigai impact structure, modified after Masaitis et al. (1980).
 (1) Archean gneisses and schists; (2) Upper Proterozoic and Cambrian quartzites, dolomites, and limestones; (3) Permian sandstones and argillites with sills and dikes of Triassic dolerites; (4) tagamites; (5) suevites with lenses of fine-grained allogenic breccia, (6) allogenic breccia; (7) center line of annular uplift; (8) center line of annular trough, (9) axes of radial troughs; (10) thrusts, faults.

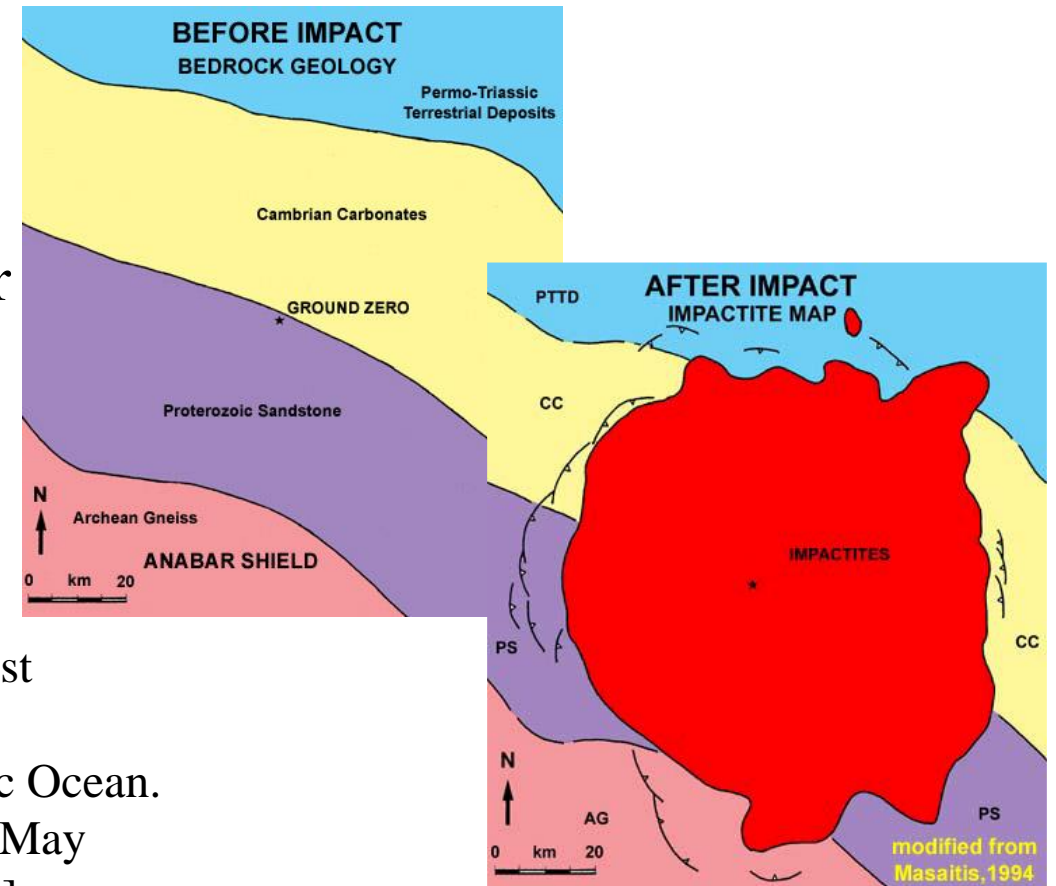

-  Archean gneisses and schists
-  Upper Proterozoic and Cambrian quartzites, dolomites and limestones
-  Permian sandstones and Triassic dolerite dykes
-  Tagamites
-  Suevites with lenses of coptoclastite
-  Allogenic breccia
-  Centre line of annular uplift
-  Centre line of annular trough
-  Axes of radial troughs
-  Thrusts, faults

Popigai

geology of the main
proved impact crater

71°38'N. 111°11'E
crater center

North Central Siberia
about 100 km from the coast
of the Laptev Sea,
an embayment of the Arctic Ocean.
Late Eocene - 35.7 (± 0.2) Ma
[by stepwise heating Ar-Ar].

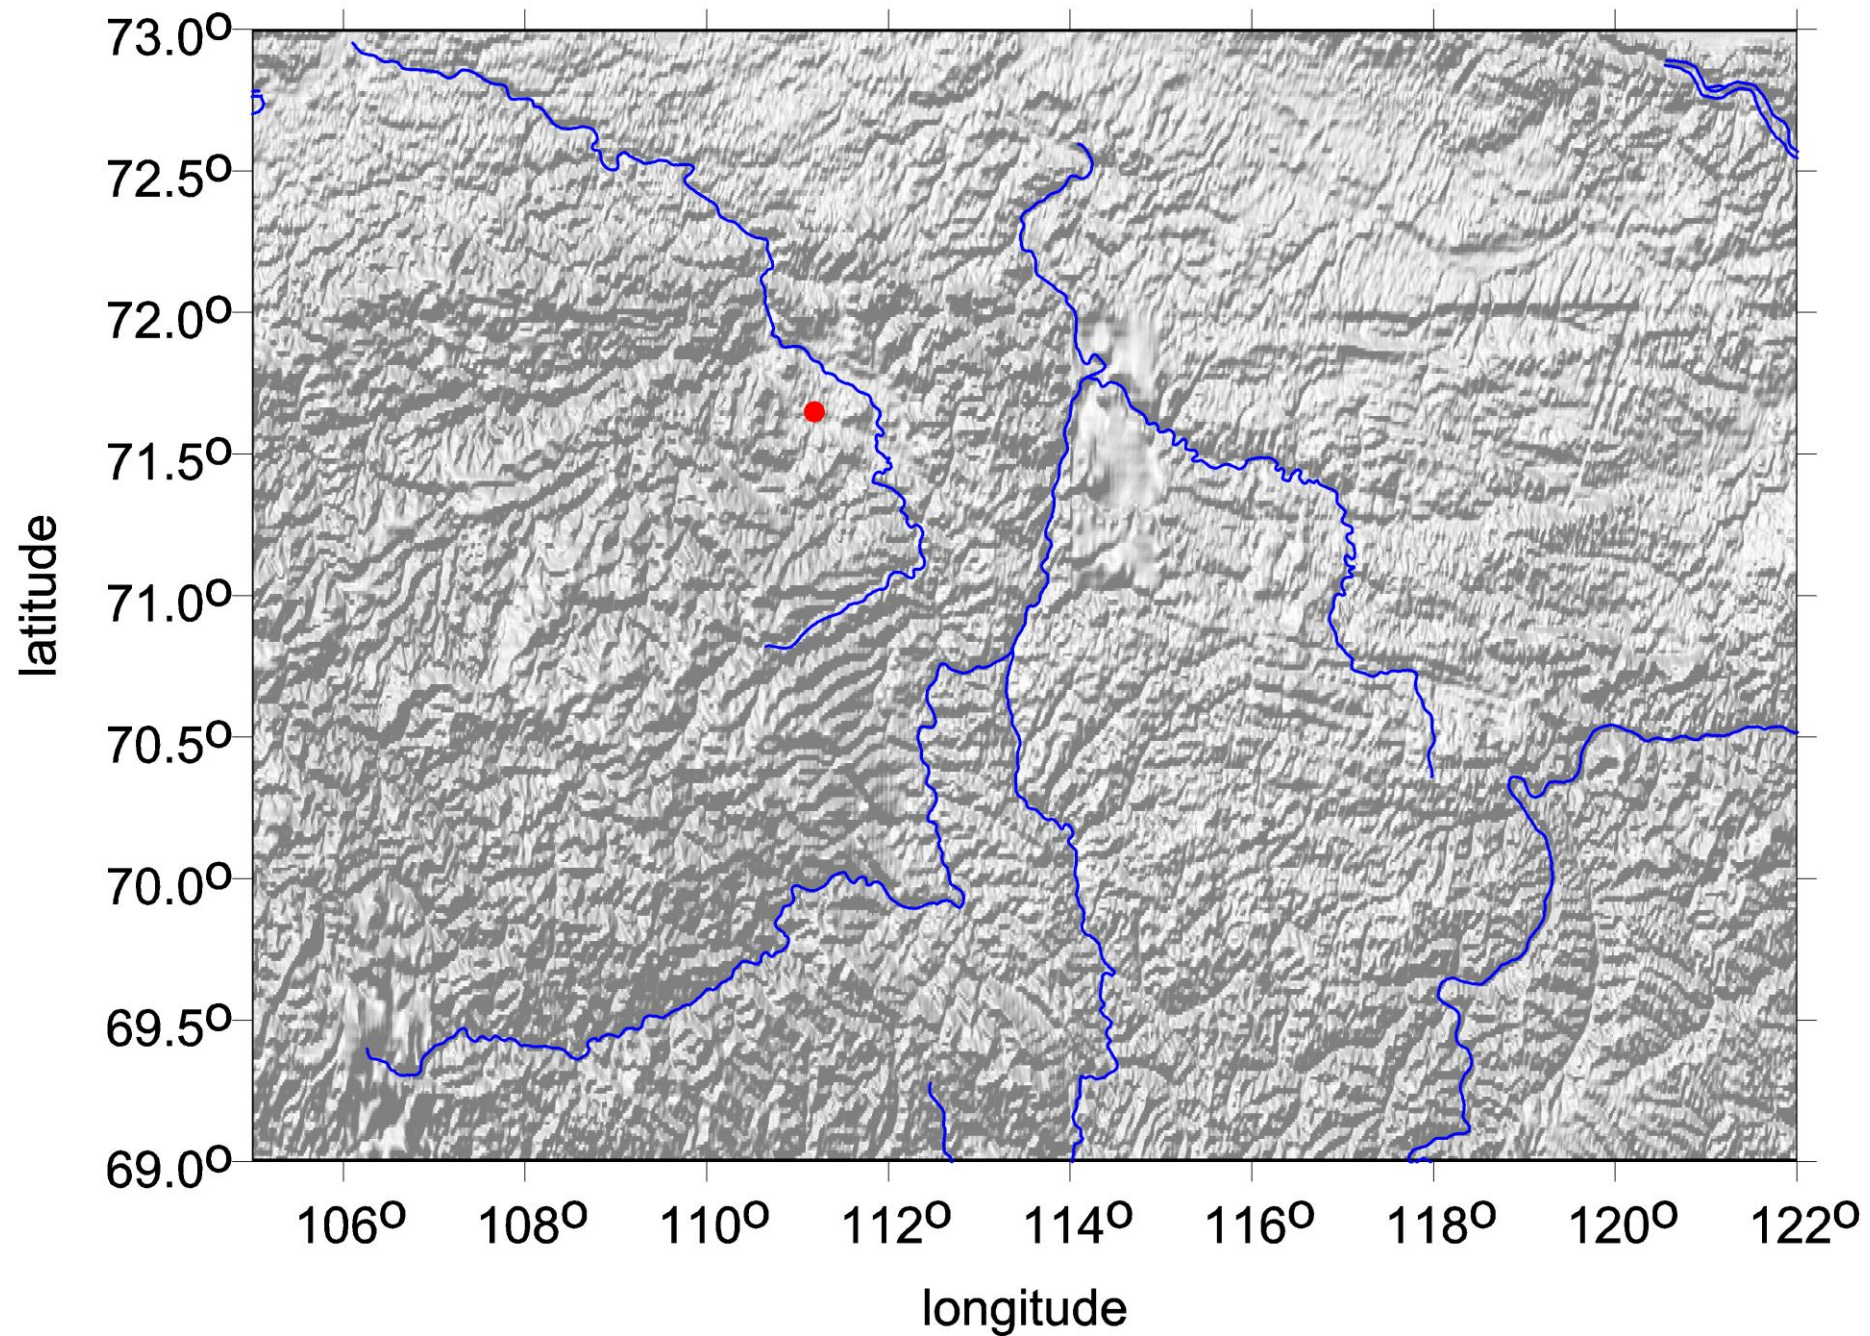

35.7-Ma-old and -100-km-wide multi-ring Popigai
a well- preserved impact structure at the Anabar shield,
central Arctic Siberia, filled with melted and shocked material
that included shock-generated impact diamonds.
Because the structure is exposed, but only slightly eroded,
a variety of impactites are preserved
and accessible for petrological studies.

Geology of the Popigai impact structure, after Masaitis (1994).
