Degradation of TFA (gas phase)					
67.	TFA + OH --> CF ₃ O ₂	Y	CF ₃ C(O)OH + OH --> CF ₃ C(O)O	9.35×10 ⁻¹⁴ (Hurley et al. 2008)	Major TFA (gas phase) loss pathway.
Wet and dry deposition of TFA					
	N/A		Dry and wet deposition will be included.		

¹ Combined with other reactions for GEOS-Chem mechanism; see the Notes/Justification column for details.

- (a) A major TFA formation pathway. Reactions 1 and 2 are combined into a single reaction in GEOS-Chem. FRO₂ collectively represents the peroxy radicals formed from CF₃CHCHF oxidation.
- (b) Reactions 3, 8, 13, and 14 are combined into a single reaction in GEOS-Chem. Rate constant based on IUPAC recommendation for similar species.
- (c) Only relevant in absence of NO; Rate constant ~10x smaller than RPO₂+NO.
- (d) Reactions 6 and 11 are combined into a single reaction in GEOS-Chem. Hydroxy-carbonyls (FRCO) are the major product in FRO₂+HO₂ reaction. Rate constant based on IUPAC recommendation for similar species.
- (e) Only relevant in absence of NO; Rate constant ~10x smaller than RSO₂+NO.
- (f) Chemical pathway not relevant with removal of RPO₂+HO₂ → RPOOH.
- (g) Reactions 18 and 23 are combined into a single reaction in GEOS-Chem.
- (h) Minor oxidation pathway; Oxidation lifetime is ~4 weeks so likely reactant will be removed by wet deposition prior to reaction with OH.

(i) Chemical pathway not relevant with removal of $\text{RSO}_2 + \text{HO}_2 \rightarrow \text{RSOOH}$.

(j) FCO_3 product does not impact TFA formation so is excluded to simplify mechanism.

(k) Rate constant based on IUPAC recommendation for similar species. Reaction involves two steps:

Low TFA yield following further reaction of CF_3CO ; influenced by NO_x concentration.

(l) Photolysis occurs via several steps but does not lead to TFA formation so only the first step is included.

(m) Competes with TFA formation pathway ($\text{CF}_3(\text{O})\text{O}_2 + \text{HO}_2$).

(n) Only relevant in absence of NO ; Rate constant $\sim 10\times$ smaller than $\text{CF}_3\text{CO}_3 + \text{NO}$.

(o) $\text{CF}_3\text{CO}_3\text{H}$ formation in $\text{CF}_3\text{CO}_3 + \text{HO}_2$ reaction is minor.

(p) TFPAN acts as reservoir species for CF_3CO_3 , with a lifetime of <1 day in the tropospheric boundary to several months at about 5 km.

(q) Reactions 36 and 37 are combined into a single reaction in GEOS-Chem.

(r) RO_2 approximated with CH_3O_2 in GEOS-Chem.

(s) These reactions do not lead to TFA formation.

(t) Can lead to TFA formation at low temperatures in the upper troposphere.

(u) HRO_2 undergoes rapid thermal decomposition at most atmospheric temperatures but slows in upper troposphere.

(v) Reactions 52, 65, and 66 are combined into a single reaction in GEOS-Chem. Rate constant based on IUPAC recommendation for similar species.

(w) Not with competitive as $\text{HRO}_2 + \text{NO}$ and $\text{HRO}_2 + \text{HO}_2$ reactions.

(x) Reactions 54, 55, and 56 are combined into a single reaction in GEOS-Chem. Rate constant based on IUPAC recommendation for similar species.

(y) Impacts TFA formation from $\text{HRO}_2 + \text{HO}_2$ reaction.

(z) Reactions 62, 65, and 66 are combined into a single reaction in GEOS-Chem.

(aa) Not relevant with removal of $\text{HRO}_2 + \text{RO}_2$ reaction.

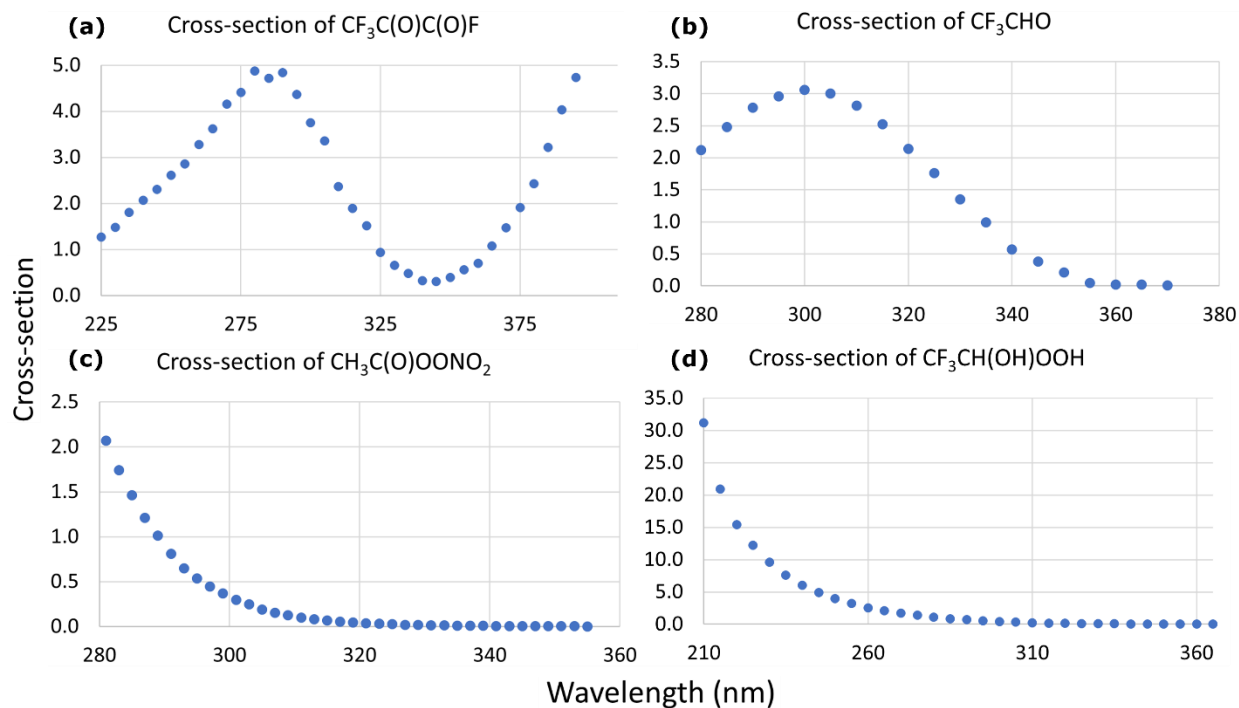

Fig. S1. Wavelength varying cross-sections ($10^{-20} \text{ cm}^2 \text{ molecule}^{-1}$) of (a) $\text{CF}_3\text{C}(\text{O})\text{C}(\text{O})\text{F}$, (b) CF_3CHO , (c) $\text{CF}_3\text{C}(\text{O})\text{OONO}_2$, and (d) $\text{CF}_3\text{CH}(\text{OH})\text{OOH}$.

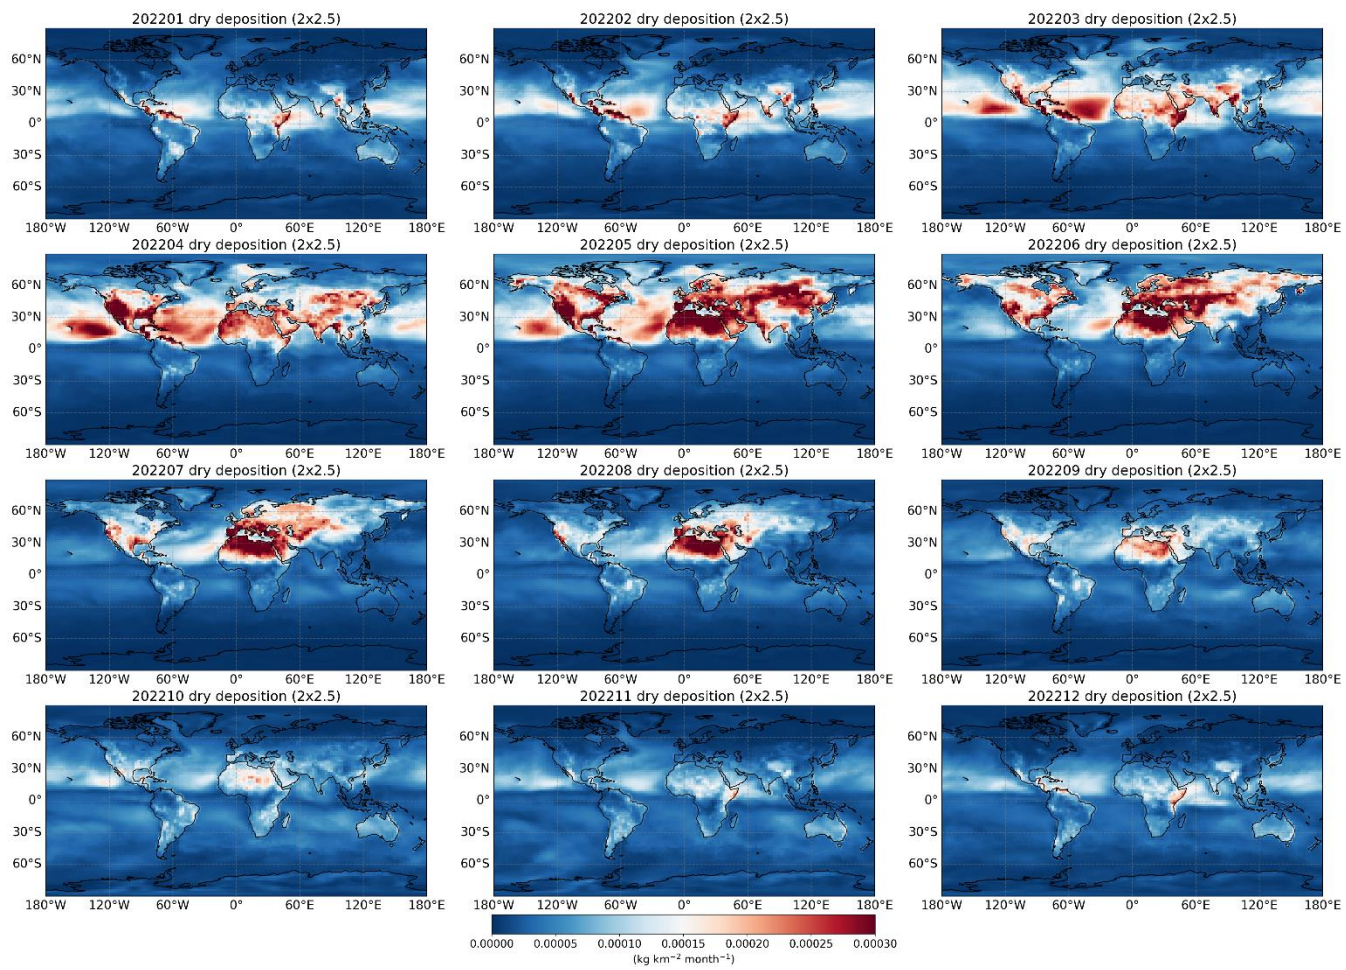

Fig. S3. Global monthly variation in dry deposition of TFA at $2 \times 2.5^\circ$ resolution. *Legend:* 202201 = January of 2022.

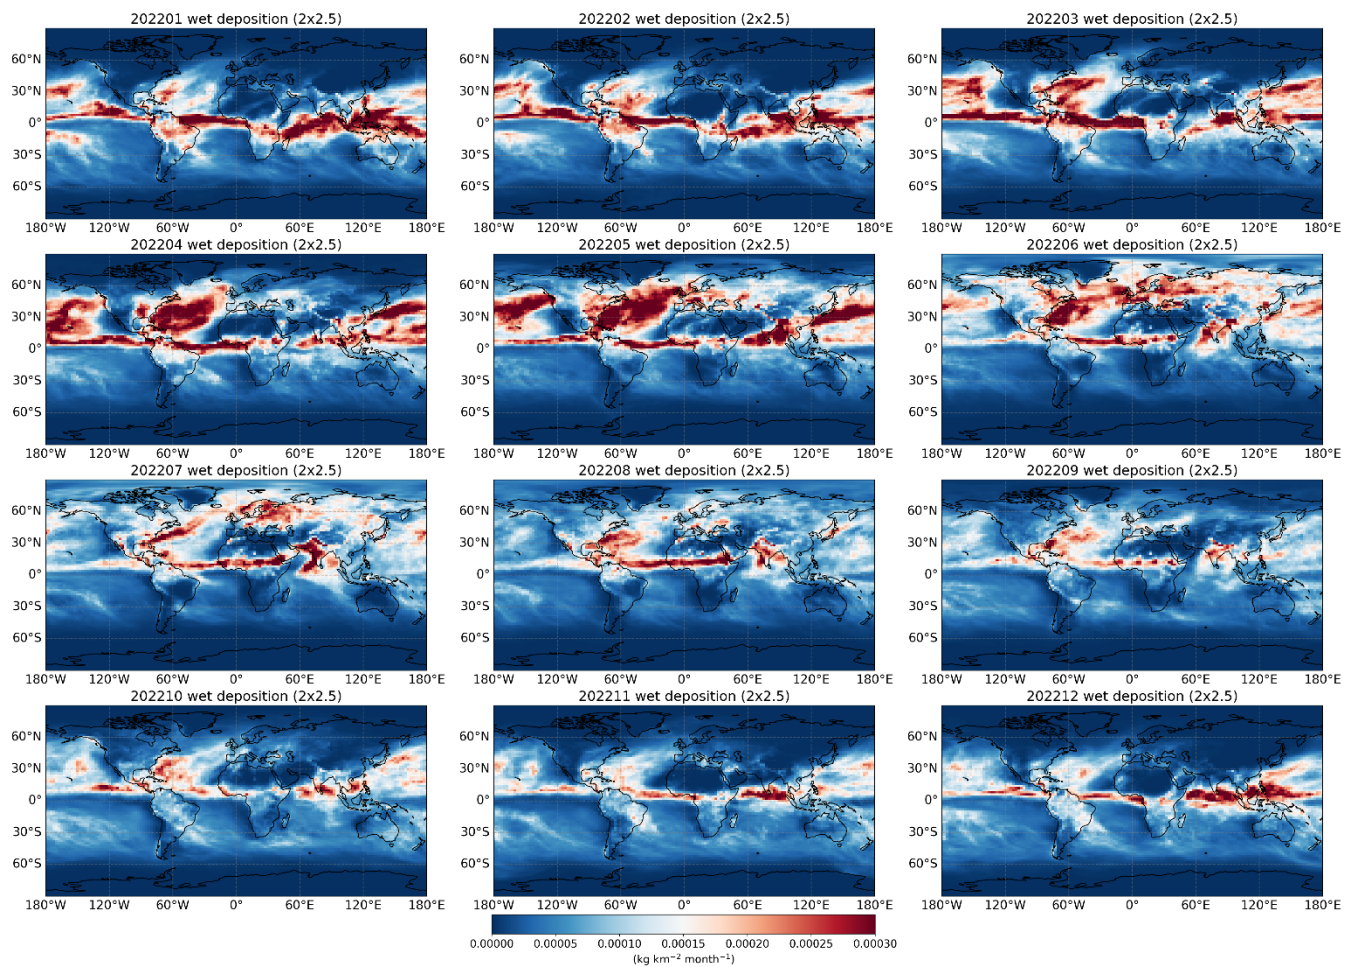

Fig. S4. Global monthly variation in wet deposition of TFA at $2 \times 2.5^\circ$ resolution. *Legend:* 202201 = January of 2022

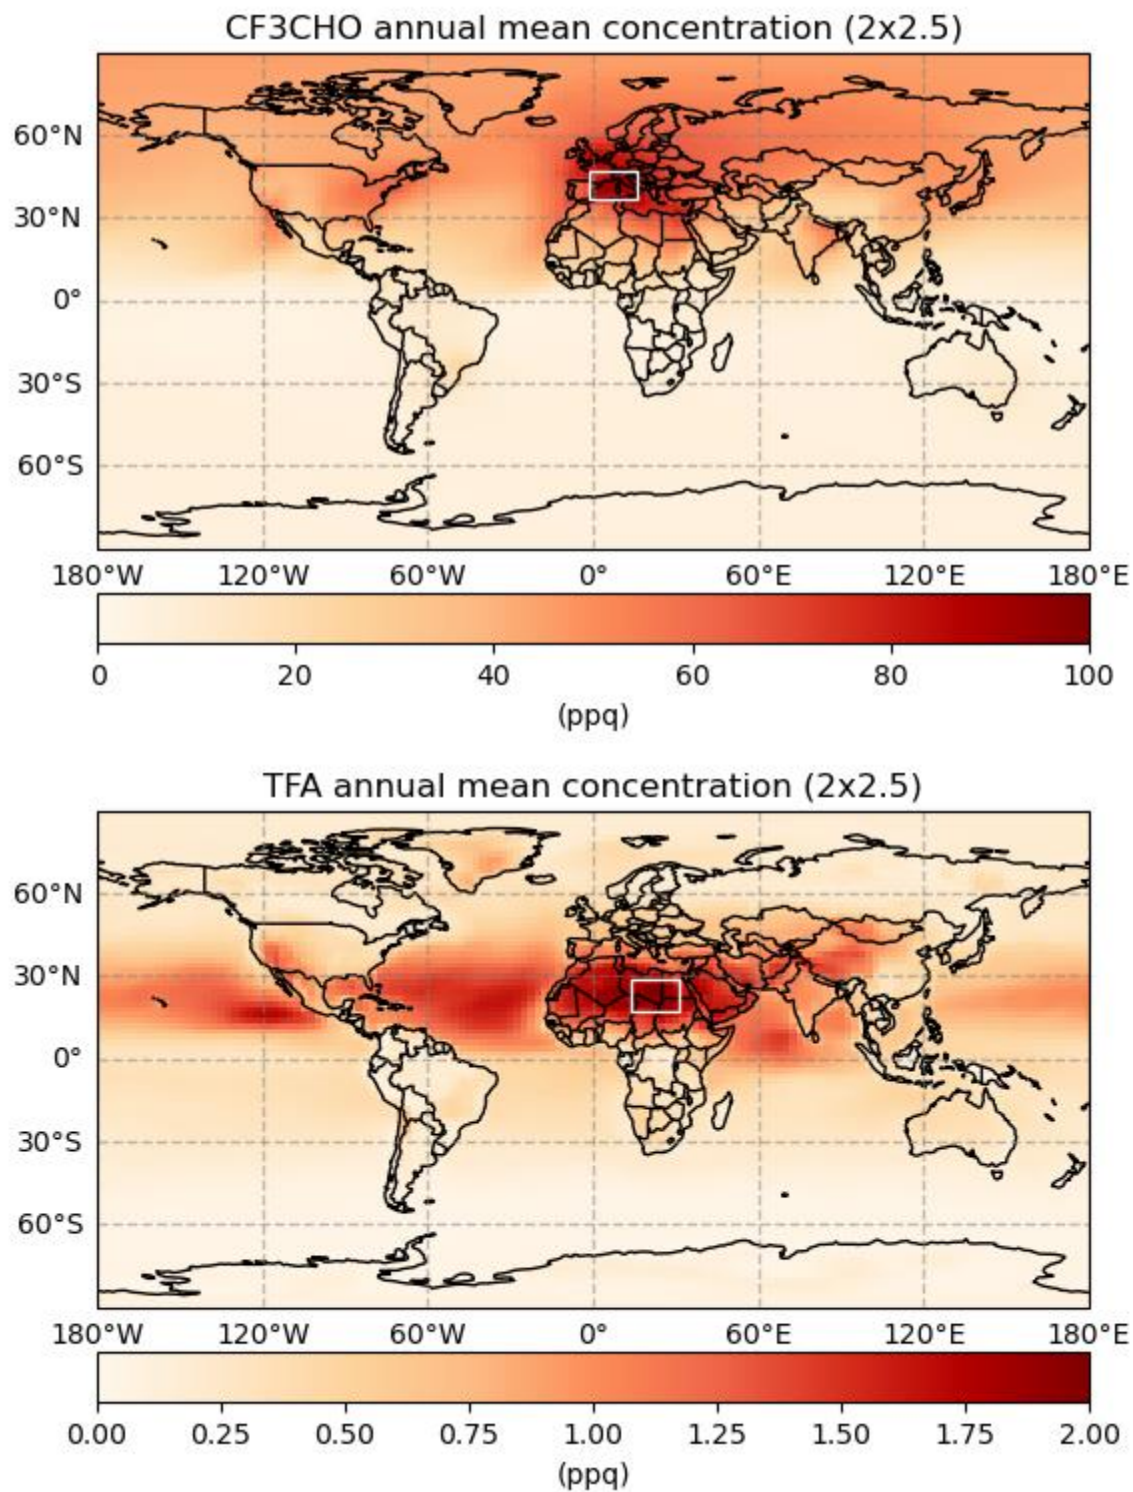

Fig. S5: Annual mean concentrations of trifluoroacetaldehyde (CF₃CHO) and trifluoroacetic acid (TFA) at 2×2.5° resolution. The white rectangle marks two regions: 1) high CF₃CHO in the northern temperate region with high pMDI sales and 2) high TFA in the tropical region with low (or no) pMDI sale.

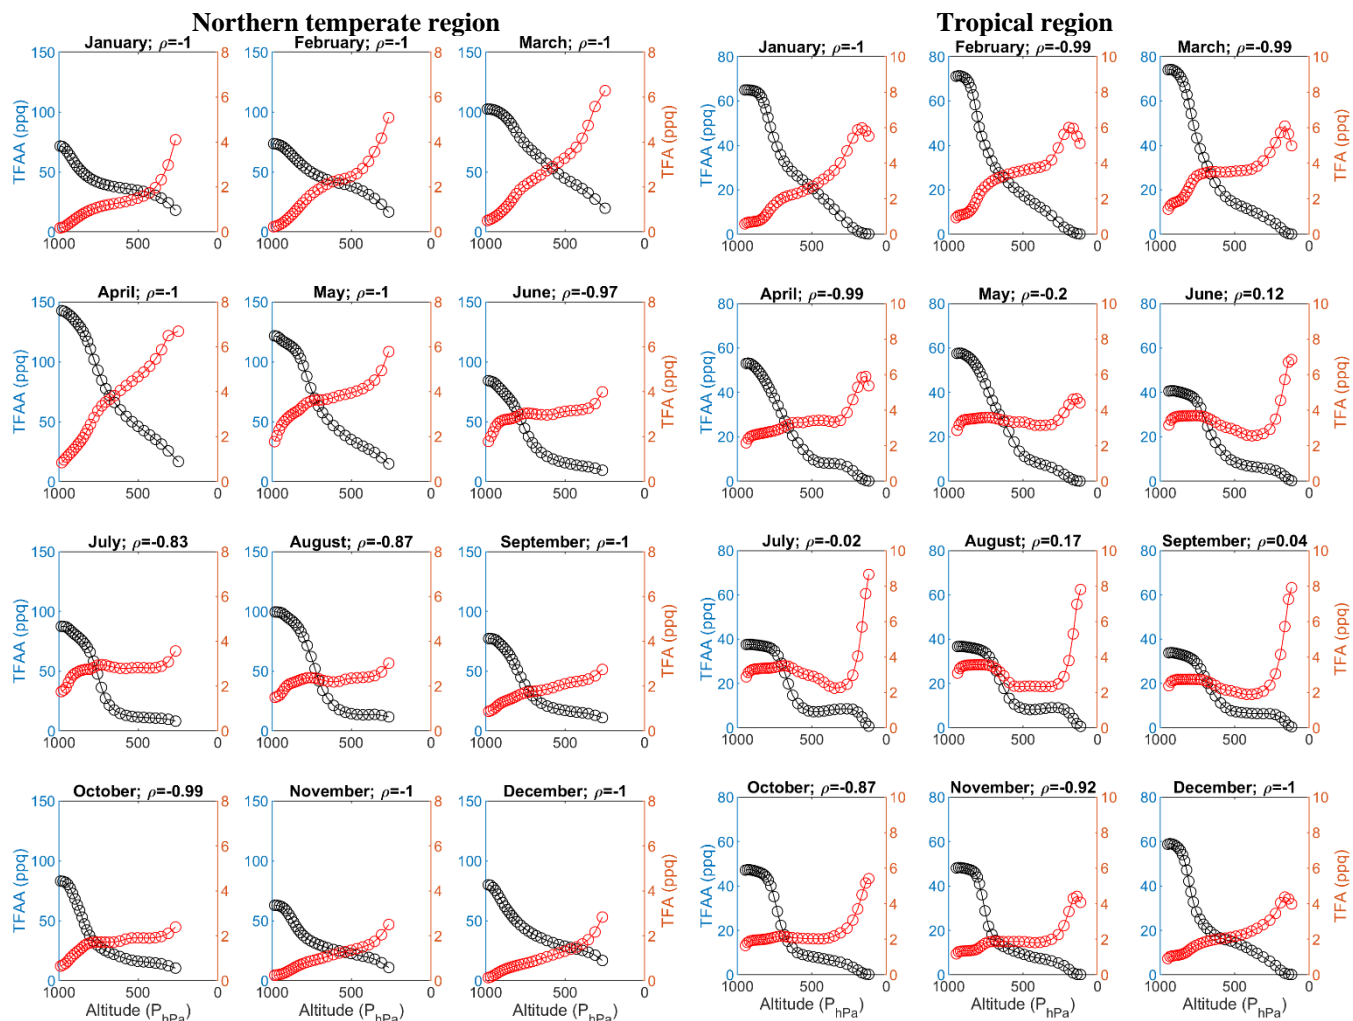

Fig. S6: Spearman Correlation (ρ) between trifluoroacetic aldehyde (TFAA) and trifluoroacetic acid (TFA) in two identified regions of Europe and Africa (Figure S5). This analysis confirms that hydroxyl radical (OH) route of TFAA is the predominant route of TFA formation. Although, under some environmental conditions, channels other than OH route may contribute to formation of gas-phase TFA.

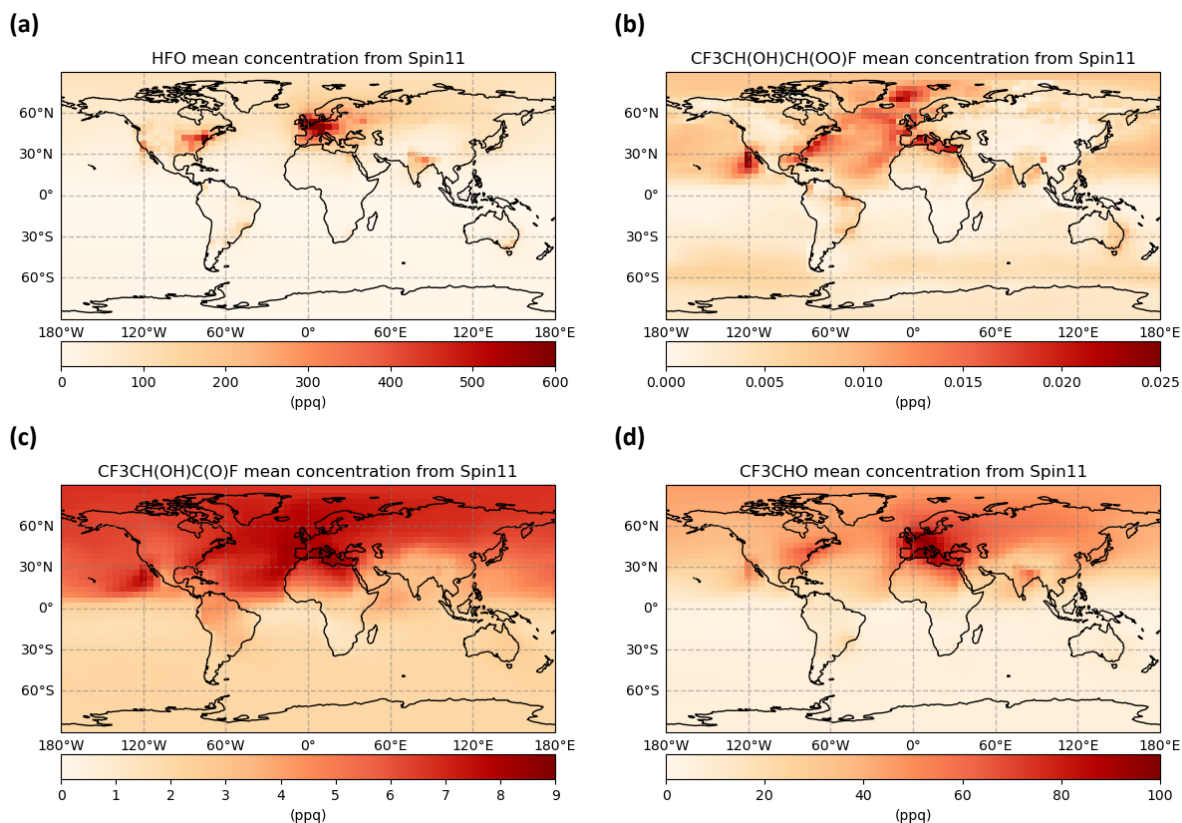

Fig. S7: Annual mean concentrations of (a) $\text{CF}_3\text{CH}=\text{CHF}$, (b) $\text{CF}_3\text{CH}(\text{OH})\text{CH}(\text{OO})\text{F}$, (c) $\text{CF}_3\text{CH}(\text{OH})\text{C}(\text{O})\text{F}$, and (d) CF_3CHO at the surface from $4^\circ \times 5^\circ$ simulation

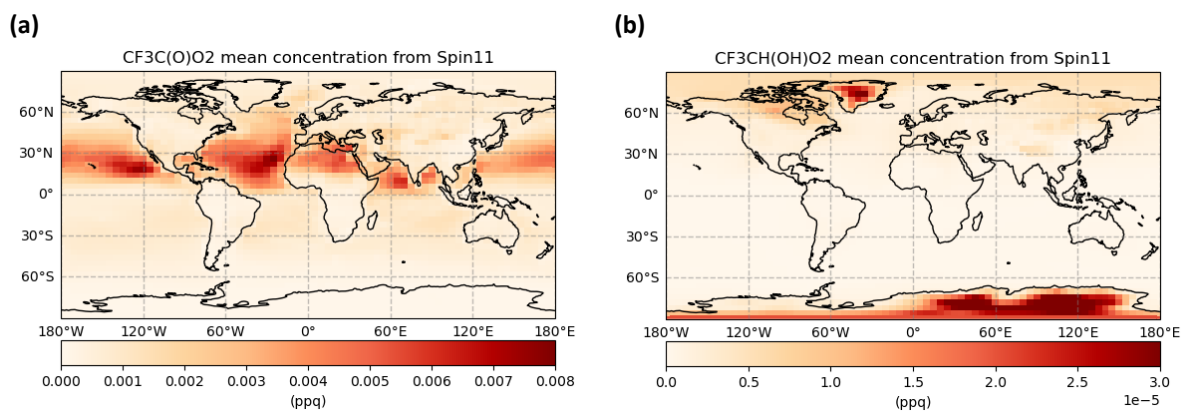

Fig. S8: Annual mean concentrations of (a) $\text{CF}_3\text{C}(\text{O})\text{O}_2$ and (b) $\text{CF}_3\text{CH}(\text{OH})\text{O}_2$ at the surface from $4^\circ \times 5^\circ$ simulation.

Section S1: Waterbody/Watershed and Other Modeling Parameters

Some default modeling parameters are used when site-specific data are not available, and these recommended values typically reflect average conditions in the respective watershed area and may not accurately represent site-specific water body conditions. These values may be more appropriate for some locations or regions, and less so for others. However, the ranges of these default parameters are either relatively narrow or the impact on the modeling results is insignificant. Other parameters were reasonably estimated based on generally available information for the sub-basins of each River. Other variables were reasonably estimated based on generally available information for each modeled river.

For example, the recommended default value for the empirical intercept coefficient has relatively small impact on the modeling results. This parameter is an estimated average value that is based on studies of sediment yields from various watersheds. Therefore, the default value may not accurately represent site-specific watershed conditions. As a result, using the default value may slightly under- or over-estimate the TFA concentrations in surface water and sediment.

The key factors that have significant impacts on the modeling results include TFA deposition rates, impervious area in the watershed, volumetric flow rate, and total infiltrations, as discussed below:

- The TFA concentration in surface water increases significantly with the increase of the watershed area; the impact on the TFA concentration in surface water due to the percentage change in the watershed area is more significant than the change in the water body because the contribution of the TFA load from the soil in the watershed is much larger than the direct deposition from the air on the water body. The watershed area estimates are based on sub-basin-specific measurements in GIS based on the available watershed data from USGS, the EU-Hydro River Network Database, and the Indian Government. The uncertainty associated with this parameter is considered low.
- The modeled TFA concentration in surface water decreases significantly when the river flow rate increases. The availability of the volumetric flow rate data at gages, the spatial coverage, and the specific gage location (on the main river vs. located at less relevant locations) all have impacts on the estimated of the volumetric flow rate and the subsequent modeled TFA concentrations in surface water. The uncertainty associated with this parameter increases when the flow rate data from gages on the mainstream of the river are limited (e.g., very few gage locations on the mainstream of the river, the spatial coverage is poor, or the measurements are limited).
- The infiltration in each sub-basin is determined by precipitation, irrigation, run-off, and average evapotranspiration. The precipitation data, in general, has less uncertainty, while the irrigation, run-off, and average evapotranspiration are often based on estimates for a relatively large region and may not be accurate for each sub-basin. The modeled TFA concentration in surface water concentration decreases significantly when total infiltration increases (assuming the same deposition rate), primarily due to increased loss of TFA in soil by leaching which results in lower TFA concentrations in soil (note that the contribution of TFA to surface water from groundwater discharge is not simulated in this model).
