

500-thousand-year-old basal ice at Skytrain Ice Rise, West Antarctica, estimated with the $^{36}\text{Cl}/^{10}\text{Be}$ ratio - supplementary information

Niklas Kappelt, Raimund Muscheler, Eric Wolff, Marcus Christl, Christof Vockenhuber

Figure S1 visualises the uncertainty of age estimates, which results from the measurement uncertainty of the $\delta^{18}\text{O}$ detrended $^{36}\text{Cl}/^{10}\text{Be}$ ratio (shown as vertical error bars) and the uncertainty of the present-day value, represented by the shaded area around the decay curve.

Figure S1: Age estimates for five deep samples of the Skytrain ice core based on the $\delta^{18}\text{O}$ detrended $^{36}\text{Cl}/^{10}\text{Be}$ ratio.

Figure S2 shows the $\delta^{18}\text{O}$ detrended and decay corrected ^{36}Cl concentration with a standard deviation of 17% of the mean. The resulting age estimates for deeper samples lack the production rate correction provided by ^{10}Be concentrations and have larger uncertainties than estimates with the $^{36}\text{Cl}/^{10}\text{Be}$ ratio, but suggest older ages for four out of five samples.

Figure S2: Age estimates for five deep samples of the Skytrain ice core based on the $\delta^{18}\text{O}$ detrended ^{36}Cl concentration.
