70 **Abstract.** This paper describes the climate-related forcings (CRFs) provided within the ‘b’ part of the third  
71 simulation round of the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP3b). While ISIMIP3a  
72 comprises historical impact models simulations forced by observational CRF and direct human forcings  
73 (DHF), the ISIMIP3b CRFs are based on climate model simulations generated within the sixth phase of the  
74 Coupled Model Intercomparison Project (CMIP6). In a first set of experiments (ISIMIP3b, group I) the  
75 CMIP6-based CRFs for the historical period are combined with historical observation-based DHF also  
76 considered in ISIMIP3a (e.g. land use patterns, water and agricultural management, and fishing efforts).  
77 These group I simulations allow for the quantification of impacts of historical climate change by  
78 comparison to simulations where the observational DHF are combined with simulated pre-industrial CRFs.  
79 In addition, the impacts of observed changes in CRFs can be compared to the impacts of simulated  
80 changes in CRFs by comparing the ISIMIP3a simulations to the ISIMIP3b, group I simulations. The second  
81 group of experiments (ISIMIP3b, group II) comprises future projections assuming constant observational  
82 direct human forcings at 2015 levels to estimate the impact of climate change given today’s direct human

83 influences for the low emission scenario SSP1-2.6, the high and the very high emission scenarios SSP3-7.0,  
84 SSP5-8.5, respectively. The very high emissions scenarios and the assumption of fixed present day direct  
85 human forcings particularly allow for testing the scalability of impacts in terms of global temperature  
86 change. The provided CRFs comprise atmospheric CO<sub>2</sub> and CH<sub>4</sub> concentrations, atmospheric and oceanic  
87 climate data, coastal water levels, tropical cyclone tracks and their associated wind speed and  
88 precipitation fields. In addition to the CRFs data, this paper describes the experiments belonging to group  
89 I and II and the rationale behind them. Another set of future projections accounting for changing DHFs  
90 (ISIMIP3b, group III) is in preparation and will be described in another paper.

91  
92

### 93 **Introduction**

94 This is the second paper of a series of three papers describing the experiments of the third simulation  
95 round of the Inter-Sectoral Impact Model Intercomparison Project ISIMIP (isimip.org). The project  
96 provides a common scenario framework for cross-sectorally consistent climate impact simulations.  
97 **Currently, operational simulation protocols exist for the following sectors: Agriculture, Biomes, Energy,**  
98 **Fire, Food security and nutrition, Groundwater, Labour, Lakes global, Lakes regional, Fisheries and marine**  
99 **ecosystems global, Fisheries and marine ecosystems local, Peatland, Permafrost, Water global, Water**  
100 **regional. Additional protocols for Coastal systems, Regional forests, Temperature-related mortality,**  
101 **health indicators, Terrestrial biodiversity and Water quality sectors are under development.** In its third  
102 round it covers i) model evaluation and climate impact attribution experiments based on observation-  
103 based climate and direct human forcings (DHF) (ISIMIP3a, first paper, (Frieler et al., 2023)), ii) climate  
104 impact simulations driven by simulated climate-related forcings (CRF) based the sixth phase of the  
105 Coupled Climate Model Intercomparison Project (CMIP6) assuming ISIMIP3a observational DHF in the  
106 historical period and fixed 2015 DHF for the future simulations (ISIMIP3b, group I+II, this paper), and iii)  
107 an upcoming set of CMIP6-based future projections where DHF vary according to given Shared  
108 Socioeconomic Pathways (SSPs) (no adaptation scenarios) and in response to climate change impacts  
109 (adaptation scenarios) (ISIMIP3b, group III). So while this paper only describes the ISIMIP3b CRF, the third  
110 paper will only address the DHFs that are still under development while the CRF of the group III simulations  
111 will be identical to the future CRF described here.

112

113 Similar to the Coupled Model Intercomparison Project (CMIP) (Eyring et al., 2016) all simulations will be  
114 freely available (<https://data.isimip.org/>) to allow for follow-up analysis. The consistent design of the  
115 simulations does not only allow for the comparison of climate impact simulations within each sector, but  
116 also enables the bottom-up integration of impacts across sectors. Thus, it provides a unique basis for the  
117 estimation of the effects of climate change on, e.g., the economy, displacement and migration, health, or  
118 water quality resolving the mechanisms along different impact channels and fully exploiting the process-  
119 understanding represented in the biophysical impact models.

120

121 Compared to ISIMIP2b, the ISIMIP3b CRF represent the following updates: i) climate forcing data based  
122 on phase 6 of the Coupled Model Intercomparison Project (CMIP6) (Eyring et al., 2016) and post-processed  
123 by an improved bias adjustment and statistical downscaling method (see section 3.2), and ii) large

124 ensembles of potential realisations of tropical cyclone tracks, wind and precipitation fields derived from  
125 two different modelling approaches assuming CMIP6 boundary conditions, while in ISIMIP2b only one  
126 approach was used and precipitation fields were not included. In addition, we plan to provide coastal  
127 water levels at high temporal resolution (upcoming). The approach to generate the data is also described  
128 here.

129  
130 The development of the ISIMIP3b protocol was coordinated by the ISIMIP-Cross-Sectoral Science Team  
131 (CSST) at the Potsdam Institute for Climate Impact Research (PIK) along the same decision process as for  
132 ISIMIP3a (Frieler et al., 2024a).

133  
134 This paper is accompanied by a simulation protocol (*ISIMIP3b Simulation Protocol*, 2023) providing all  
135 technical details such as file and variable naming conventions, as well as sector-specific output variables  
136 to be reported by the participating modelling teams. This paper refers to the protocol version of December  
137 21st, 2023. However, as the protocol may still be updated due to addition of new variables, correction of  
138 errors, or the inclusion of new sectors, contributors to ISIMIP should always refer to [protocol.isimip.org](http://protocol.isimip.org)  
139 for the most up to date reference for planned impact model simulations.

140  
141 The ISMIP3a and ISIMIP3b protocols have been jointly developed and participation in ISIMIP3 requires  
142 contribution to both ISIMIP3a and ISIMIP3b, using the same impact model versions in order to allow for  
143 the evaluation of the impact models future projections in ISIMIP3b.

144  
145 In the following, we describe the rationale behind the individual scenario set-ups (section 1). We then  
146 introduce the individual climate-related forcing data sets in the second section covering atmospheric  
147 climate data including lightning and tropical cyclones tracks, wind and precipitation fields; ocean data;  
148 coastal water levels; and atmospheric CO<sub>2</sub> as well as CH<sub>4</sub> concentrations.

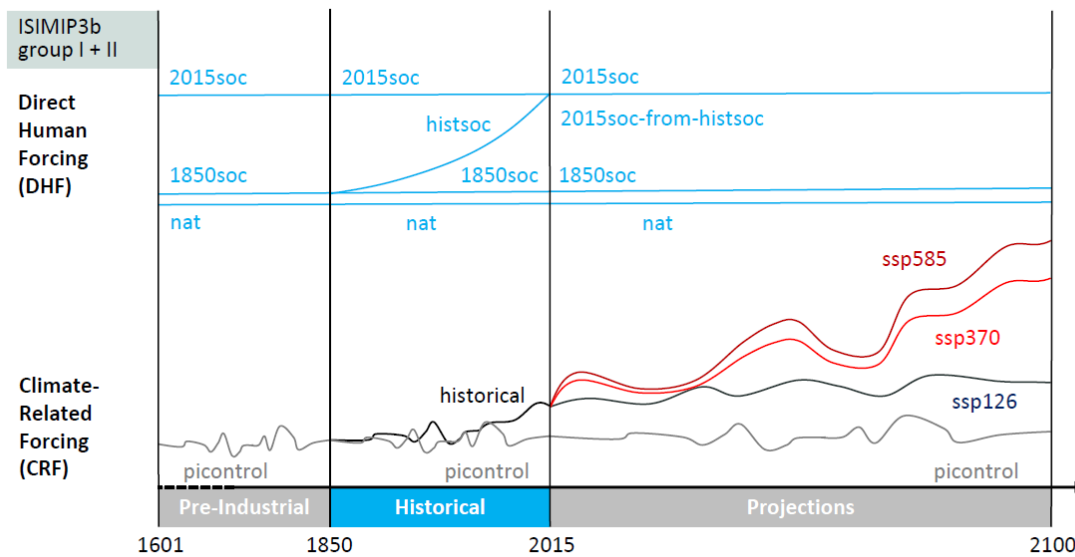

## 150 **1 Experiments and underlying rationale**

151  
152 The selection of the scenarios is a community-driven process constrained by the availability of climate  
153 model simulations (multi-GCM ensemble per scenario) and socio-economic background information (such  
154 as land use patterns, populations and GDP data etc. additionally required as 'Direct Human Forcing' for  
155 the ISIMIP3b, group III impact model simulations that will be introduced in an upcoming paper). These  
156 criteria have made CMIP6-ScenarioMIP the reference point for the selection (O'Neill et al., 2016). The  
157 selection of ISIMIP3b scenarios (see **Figure 1**) from the four ScenarioMIP Tier 1 scenarios was additionally  
158 driven by the aim to capture a wide range of possible futures from low to high emission scenarios and to  
159 provide of a long baseline simulation assuming pre-industrial climate conditions that allows for a robust  
160 estimation of reference return levels of extreme events. This is why the original selection comprised the  
161 pre-industrial baseline ('picontrol'), the historical simulations ('historical'), SSP1-2.6 representing the 'low  
162 end of the range of future forcing pathways in the IAM literature' (O'Neill et al., 2016), and SSP5-8.5  
163 representing the 'high end of the range of future pathways in the IAM literature' (O'Neill et al., 2016).  
164 Given recent mitigation efforts, some estimates of recoverable coal reserves, and decreasing prices for

165 renewable energies the emissions underlying SSP5-8.5 have been criticised for being unplausibly high  
166 (Hausfather & Peters, 2020). Based on these discussions, the ‘medium to high end of the range of future  
167 forcing pathway’ SSP3-7.0 (O’Neill et al., 2016) has been added to the ISIMIP3b scenario set-up. While this  
168 scenario is described as ‘average no climate protection policy’ by (Hausfather & Peters, 2020), we highlight  
169 that we explicitly not describe it as a ‘business as usual scenario’ and that this was not the framing within  
170 ScenarioMIP either. Instead SSP3-7.0 is based on rather extreme assumptions about land use changes and  
171 aerosol emissions e.g. leading to a scaling of precipitation with global mean temperature that diverges  
172 from the scaling identified in the other scenarios (Shiogama et al., 2023). In addition, SSP5-8.5 is explicitly  
173 kept in the ISIMIP3b ensemble as its particularly strong warming signal allows testing to what degree the  
174 simulated impacts of climate may scale with global mean temperature, which could allow for a translation  
175 of impacts to other emission scenarios. In addition, even under lower emission scenarios, global warming  
176 levels as the ones reached under SSP5-8.5 in 2100 will eventually be reached later in time as long as  
177 emissions are not reduced to zero. These impacts of high warming levels would not be captured when  
178 only considering lower emission scenarios ending in 2100.

179  
180 All ISIMIP experiments are determined by the underlying set of CRFs and DHF, where each package of CRF  
181 and DHF has a specific label that will then be included in the output file names to allow for an identification  
182 of the experiments they belong to. The individual experiments are defined by the combination of both  
183 types of forcing data sets, where the associated specifiers are indicated in brackets in the subheadings  
184 naming the experiments (CRF specifier + DHF specifier). The different combinations of the default sets of  
185 ISIMIP3b CRFs (‘picontrol’, ‘historical’, ‘ssp126’, ‘ssp370’, and ‘ssp585’) and DHF (‘histsoc’, ‘2015soc’,  
186 ‘1901soc’, ‘1850soc’, ‘nat’, and ‘2015soc-from-histsoc’) are sketched in **Figure 1** and described in more  
187 detail below.

188  
189 The CRF data described in this paper are mandatory; i.e. if impact models consider this forcing, the  
190 specified dataset must be used; if an alternative input data set is used instead, the run cannot be  
191 considered an ISIMIP3b, group I + II simulation. The DHF for the historical period is identical to the  
192 ISIMIP3a DHF listed in **Table 1** of (Frieler et al., 2024a) where we also indicate whether the data set is  
193 mandatory or optional. Optional forcing data could be used but is not mandatory. In addition, the protocol  
194 includes a set of sensitivity experiments that are described as deviations from the default runs and labelled  
195 by the baseline CRF and DHF settings and a third specifier indicating the deviation from this default setting.  
196 The ISIMIP3b group I+II sensitivity runs include experiments with fixed levels of atmospheric CO<sub>2</sub>  
197 concentrations (‘2015co2’), high levels in CO<sub>2</sub> concentrations in combination with low levels of climate  
198 change (‘ssp585co2’), and runs with lightning data that vary in response to climate change (‘varlightning’),  
199 while lightning is fixed at present day levels in the default runs. These sensitivity experiment runs are not  
200 depicted in **Figure 1** but listed in **Table 2**.

203  
204  
205  
206  
207  
208  
209

**Figure 1:** Illustration of the default ISIMIP3b forcing data sets. Each ISIMIP3b experiment is defined by a combination of a CRF data set with a DHF data set. The considered combinations are listed in **Table 2** and the underlying rationale is described in section **1.1** and **1.2**. **Table 1** lists all data sets defining the considered CRFs while the DHFs are based on the same datasets as in ISIMIP3a. Potentially required spin-up procedures are not included in the Figure, but described in section **1.1**.

The ISMIP3b simulations are divided into two groups. Group I comprises the simulations from 1601 - 1849 (pre-industrial) and 1850 - 2014 (historical) assuming simulated pre-industrial and historical CRFs and different constant ('nat', '1850soc', and '2015soc') or varying ('histsoc') levels of DHF based on the same observational data used in ISIMIP3a (see **Figure 1**). Group II comprises the future projections assuming constant 2015 levels of DHF (see **Figure 1**) including a baseline with pre-industrial CRF (grey line in the future projections part of **Figure 1**). All experiments are introduced in more detail below (section **1.1** for group I and **1.2** for group II).

In contrast to ISIMIP3a, the CRFs provided for ISIMIP3b currently only comprise atmospheric (see section **2.1**) and oceanic climate data (see section **2.4**), tropical cyclone tracks with associated wind and precipitation fields (see section **2.2**), and CO<sub>2</sub> and methane concentration (see section **2.5**). We do not yet provide associated coastal water levels (see section **2.2.3** for planned work), and lightning data (see [Table 511](#)). Impact simulations that rely on the missing forcings cannot be generated within ISIMIP3b yet, but we are currently developing their setup and will provide the forcings as soon as possible. The ISIMIP3b atmospheric and oceanic climate data is derived from five different General Circulation Models (GCMs) generated within the Coupled Model Intercomparison project, phase 6 (CMIP6).

**Table 1: Climate-Related Forcing datasets for ISIMIP3b.**

Forcing	Status	Source, description
---------	--------	---------------------

Climate-related forcings ('picontrol', 'historical', 'ssp126', 'ssp370', 'ssp585')		
Atmospheric forcings ('picontrol', 'historical', 'ssp585', 'ssp370', 'ssp126')		
Gridded atmospheric climate forcing	mandatory	Bias-adjusted data (pre-industrial climate, historical climate, and future projections for the SSP1-2.6, SSP3-7.0, and SSP5-8.5 scenarios) generated by GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL within CMIP6 (Lange & Büchner, 2021), see section 2.1
Local atmospheric climate forcing for lakes	mandatory	Atmospheric data extracted from the data sets above for 72 lakes that have been identified within the lake sector as locations (grid cell of the ISIMIP 0.5° grid, <a href="#">ISIMIP3 local lake sites</a> ) where models can be calibrated based on observed temperature profiles and hypsometry within ISIMIP3b (depth and area) (Lange and Büchner 2021)
Tropical cyclone tracks with wind and precipitation fields	mandatory	<p><del>Available on request (see section 2.2)</del>, samples of synthetic tropical cyclone tracks derived from the five CMIP6 GCMs considered within ISIMIP generated by two different statistical downscaling approaches, see section 2.2.</p> <p>MIT approach (Emanuel et al., 2008, 2025):</p> <ul style="list-style-type: none"> <li>• <a href="#">pre-industrial climate from IPSL-CM6A-LR, MPI-ESM1-2-HR and MRI-ESM2-0 (all 1850-2014), and from UKESM1-0-LL (1950-2100)</a></li> <li>• historical climate from IPSL-CM6A-LR, MPI-ESM1-2-HR, UKESM1-0-LL and GFDL-ESM4 (all 1850-2014), and from MRI-ESM2-0 (1950-2014).</li> <li>• Future climate: <a href="#">ssp126 (2061-2100)</a>, <a href="#">ssp370 (2015-2100)</a> and <a href="#">ssp585 (2015-2100)</a> from IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, UKESM1-0-LL, and <a href="#">ssp585 (2061-2100)</a> from GFDL-ESM4.</li> </ul> <p>Two different configurations (SD and CRH, see section 2.2) of the Columbia HAZard model (CHAZ, Lee et al., 2018, 2025):</p> <ul style="list-style-type: none"> <li>• <del>pre-industrial climate (1601-2100) from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL.</del></li> <li>• historical climate (1850-2014) from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL</li> <li>• future climate (2015-2100): <a href="#">ssp126</a>, <a href="#">ssp370</a>, <a href="#">ssp585</a> from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-L</li> </ul>

		For tracks generated by the MIT approach, we also provide wind and precipitation fields (Quesada-Chacón et al., 2025)
Lightning	mandatory	Flash Rate Monthly Climatology <del>from (Cecil, 2006)</del> , not changing with climate change (Cecil, 2006)
Oceanic forcings ('picontrol', 'historical', 'ssp585', 'ssp370', 'ssp126')		
Oceanic climate forcing	mandatory	Uncorrected data (pre-industrial climate, historical climate, and future projections for the SSP1-2.6, SSP3-7.0, and SSP5-8.5 scenarios) generated by GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, and UKESM1-0-LL within CMIP6 (Büchner 2024), see section 2.4
Coastal water levels		
Coastal water levels	mandatory	In section 2.3 we describe a method to generate relative sea level projections that smoothly extend tide gauge observations into the future building on a Bayesian model (Perrette & Mengel, 2025). For ISIMIP3, we plan to extend the framework to all coastlines and directly use ISIMIP GCM output for the global thermodynamic and local stereodynamic components, adjusting the gridded simulations to associated observations to ensure a consistent transition from the historical period. Ice sheet and glacier contributions are incorporated through spatial fingerprints, while unresolved vertical land motion processes are estimated from residuals at tide gauges and extrapolated where no observations are available. We are also developing an approach to extend the sea level projections to daily maximum water levels derived from the ISIMIP3 atmospheric forcings (daily mean Surface Air Pressure and daily mean Near-Surface Wind Speed).
Atmospheric composition or fluxes		
Atmospheric CO <sub>2</sub> concentration	mandatory	(Büchner & Reyer, 2022) based on the following sources: 1850-2005: (Meinshausen et al., 2011); 2006-2014: Global annual CO <sub>2</sub> from NOAA Global Monthly Mean CO <sub>2</sub> (Lan et al., 2023); 2015-2100: (Meinshausen et al., 2020)
Atmospheric CH <sub>4</sub> concentration	mandatory	(Büchner & Reyer, 2022) based on the following sources: 1850-2014:(Meinshausen et al., 2017); 2015-2100: (Meinshausen et al., 2020)
Climate-Related Forcings for the sensitivity experiment 'varlightning', using above forcing data except for:		

Lightning data ('varlightning')		
Varying lightning according to climate change	mandatory	Lightning data has been generated for the ssp126, ssp370, and ssp850 climate projections from UKESM1-0-LL (Kaplan et al., 2023)
Climate-Related Forcings for the 'de-biased' sensitivity experiment		
Global oceanic forcings		
Oceanic forcings based on de-biased atmospheric forcings	mandatory	<u>In section 2.4.2 we describe an approach to de-bias the oceanic forcings based on the ocean biogeochemistry model NEMO-PISCES forced by a de-biased version of the IPSL-CM6A-LR-based atmospheric forcing as an option to fulfil the demand for de-biased ocean data we would like to follow.</u> <del>Not available yet, simulated by the ocean biogeochemistry model ocean biogeochemistry NEMO-PISCES forced by a de-biased version of the IPSL-CM6A-LR-based atmospheric forcing (see section 2.4.2)</del>
Regional oceanic forcings		
De-biased oceanic forcing based on observed oceanic data for individual variables and regions	mandatory	<u>The regional models of the fisheries and marine ecosystem sector have applied regional bias-adjustments within their impact simulations that are described in section 2.4.3 and that make these simulations part of the 'de-biased' sensitivity experiment in the sector (see Table 2) while the default experiments are based on the raw oceanic forcings.</u> <del>Not centrally provided, see section 2.4.3</del>

## 1.1 ISIMIP3b, group I: Climate-model based impact model simulations for the period from 1601 to 2015

The group I experiments cover the years 1601-1849 with pre-industrial CRFs ('picontrol') and fixed 1850 direct human forcings ('1850soc') described in the grey column 3 of the ISIMIP3b scenario **Table 2** as well as the subsequent years 1850-2014 considering pre-industrial and historical CRFclimate-related forcings ('picontrol' or 'historical') and different assumptions about DHFdirect human forcings ('histsoc', '2015soc', '1850soc', and 'nat') as described in the grey column 4 of **Table 2**. The reasoning behind the individual experiments are introduced below.

**Pre-industrial reference simulations (picontrol + histsoc, picontrol + 2015soc, picontrol + 2015soc-from-histsoc, picontrol + 1850soc, picontrol + nat; default):** To estimate the impacts of historical and future changes in the CRFs, the protocol includes reference simulations based on pre-industrial CRFs and DHF identical to those considered in the climate change scenario runs. In order to allow for the fitting of

244 extreme value distributions such as Gumble or Generalized Extreme Value (GEV) distributions to, e.g.  
245 annual maximum discharge to estimate reference 100 year return levels ~~of certain impacts~~, the runs are  
246 designed to ~~-include~~includes the generation of large samples (at least 250 years) of impact distributions  
247 distribution based on stable pre-industrial CRFs (picontrol) and constant DHFs (see ‘picontrol + 1850soc’,  
248 ‘picontrol + 2015soc’, and ‘picontrol + nat’ experiments in **Table 2**).

249 In addition, the protocol includes a reference experiment for the historical period (1850-2014) with DHF  
250 changing over time (histsoc) and 1850-2014 pre-industrial CRF (picontrol), while fixed 2015 DHF is  
251 considered afterwards (2015-2100) (‘picontrol + 2015soc-from-histsoc’). This run may be different from  
252 the ‘picontrol + 2015soc’ simulation for this time window because of the lagged effects of increasing DHF  
253 from 1850 to 2014. The ‘histsoc’ DHF is identical to ISIMIP3a (Frieler et al., 2024a).

254 The complete pre-industrial reference runs are divided in two parts. Only the first parts from the start  
255 until 2014 belong to group I (grey fields in Table 2~~the table~~), while the second parts covering the period  
256 2015-2100 belong to group II (red parts of ~~the t~~Table 2).

257  
258 Comparing these reference simulations to the scenario experiments using historical CRFs (historical +  
259 histsoc, historical + 2015soc, historical + 1850soc, historical + nat; default (see below)) allows for the  
260 estimation of the effects of simulated historical climate change conditional on the assumed DHF. The  
261 historical CRFclimate-related forcing (‘historical’) starts from the pre-industrial climate simulation in 1850,  
262 i.e. the ‘picontrol’ and ‘historical’ versions of the experiments have a common starting point. As some  
263 impact indicators may have ‘internal’ trends not necessarily forced by external drivers (e.g. re-growth of  
264 forests), the comparison of the 1850-2014 impact simulations forced by the ‘historical’ CRF to parallel  
265 simulations using the ‘picontrol’ CRF is more appropriate to estimate the effects of historical climate  
266 change than comparing an early period of the historical impact simulation to the end of the historical  
267 period.

268 For models requiring a spin-up, the ‘picontrol’ CRFs should be used in combinations with DHF i) at 1850  
269 levels to spin-up for the ‘1850soc’ and ‘histsoc’ experiments, ii) at 2015 levels to initialise the ‘2015soc’  
270 experiment, and iii) set to zero to start the ‘nat’ experiments. For the spin-up the ‘picontrol’ CRF should  
271 be copied as often as needed. The ‘picontrol + 1850soc’ run from 1601-1849 is part of the regular  
272 experiments that should be reported and hence the spin-up has to be finished before this pre-industrial  
273 period.

274 To allow for a quantification of the impacts of the anthropogenic CRFs, we also support historical  
275 reference simulation assuming only natural CRF (‘hist-nat’ simulations generated within the Detection and  
276 Attribution Model Intercomparison Project (DAMIP) as sub-MIP of CMIP6, (Gillett et al., 2016) by providing  
277 the associated bias-adjusted CRF as secondary climate input data (Lange et al., 2023). However, associated  
278 simulations are not an official part of ISIMIP3b and not described in the associated protocol.

279  
280 **Standard historical simulations based on historical climate-related forcing and observed changes in**  
281 **direct human forcing (historical + histsoc; default):** The historical simulations (1850-2014) are forced by  
282 historical (‘historical’) CRFs and DHFs evolving according to observations (ISIMIP3a ‘histsoc’ DHF). The  
283 ISIMIP3b ‘historical + histsoc’ experiment is comparable to the default ‘obsclim + histsoc’ run used in  
284 ISIMIP3a but based on simulated CRFs. The simulated climate is different from the observed realisation

285 due to differences in the internal variability of the observed and simulated historical climate and potential  
286 deficits in the climate model simulations. A comparison between the default ISIMIP3b ‘historical + histsoc’  
287 impact model simulations to the associated ISIMIP3a results allows for a quantification of the effects of  
288 the discrepancies between the observed and simulated CRFs on the considered impact indicators. This  
289 experiment can be initialised from the spin-up of the associated pre-industrial reference simulation in  
290 case a spin-up is needed.

291  
292 **Simulations with historical climate-related forcing and fixed 2015 direct human forcing (historical +**  
293 **2015soc; default):** This historical experiment is similar to the standard historical experiment except that  
294 it is forced by fixed 2015 DHF. It is introduced into the ‘first priority’ scenario-set-up to generate an  
295 ensemble of historical cross-sectorally consistent impact simulations that is as large as possible by not  
296 excluding impact models that are not able to handle varying DHF. If a spin-up is needed the experiment  
297 can be initialised from the spin-up of the associated pre-industrial reference simulation (picontrol +  
298 2015soc, default) described at the beginning of this section.

299  
300 **Simulations with historical climate-related forcing and fixed 1850 direct human forcing (historical +**  
301 **1850soc; default):** This historical experiment is also similar to the standard historical experiment but it is  
302 forced by the fixed 1850 DHFs. It corresponds to the ‘obsclim + 1901soc’ simulation of ISIMIP3a. Here in  
303 ISIMIP3b we consider the year 1850 instead of 1901 used in ISIMIP3a as this is the year where the  
304 ‘historical’ climate simulations with observed natural and human forcings start, i.e. a branch from the pre-  
305 industrial climate simulations assuming constant pre-industrial forcings (‘picontrol’). If a spin-up is  
306 required it does not have to be newly generated as it is identical to the spin-up for the default ‘picontrol  
307 + 1850soc’, ‘picontrol + histsoc’, and ‘historical + histsoc’ experiments and described in the beginning of  
308 this section.

309  
310 **Simulations with historical climate-related forcing and no direct human forcings (historical + nat;**  
311 **default):** Considering no ~~DHFdirect human forcings~~ (nature run) allows quantifying the effect of the  
312 simulated historical climate change conditional on otherwise natural conditions, i.e. no direct human  
313 influences on land use, water management etc.. This experiment is introduced as a companion  
314 experiment to the ‘obsclim + nat’ simulations of ISIMIP3a. The comparison with the three historical  
315 simulations with constant ~~DHFdirect human forcings~~ allows testing, to what degree the impact of climate  
316 change on the simulated natural or human systems is conditional on the underlying ~~DHFdirect human~~  
317 ~~forcing~~. This experiment is only included for the biomes and fisheries and marine ecosystems fisheries  
318 sectors as models from other sectors usually need some basic information such as vegetation patterns  
319 that are not available for natural-only conditions. The biomes models generate their own natural-only  
320 vegetation patterns based on their dynamic representation of vegetation. A spin-up does not have to be  
321 newly generated but is identical to the spin-up for the ‘picontrol + nat’ experiment described above.

322  
323 **‘De-biased’ sensitivity simulations within the marine ecosystems and fisheries sector (FishMIP) with de-**  
324 **biased historical oceanic forcings and no or histsoc direct human forcings (historical + nat, historical +**  
325 **histsoc; de-biased):** So far, the default oceanic forcing is not bias-adjusted as globally the observational

326 data are ~~too sparse~~ ~~to sparse~~ to be used in a similar empirical way as for the bias-adjustment of the  
327 atmospheric forcing. However, the biases in the forcing are expected to also induce biases in the historical  
328 and future impact simulations. To quantify these effects and to test a suggested bias-adjustment method  
329 based on comprehensive ocean-biogeochemistry model simulations forced by bias-adjusted atmospheric  
330 forcings we include a sensitivity experiment where the default [CRFclimate-related forcing](#) is replaced by  
331 input data generated by a dynamical de-biasing approach (Lengaigne et al., 2025) using the NEMO-PISCES  
332 physical-biogeochemical ocean model (Madec, 2015), which is the oceanic component of the IPSL-CM6A-  
333 LR climate model. Thus, the forcing data will first be generated for IPSL-CM6A-LR, but later extended to  
334 other ISIMIP-GCMs as described in subsection **2.4.2**.

335 In contrast, the oceanic forcing for the regional component of the marine ecosystems and fisheries sector  
336 have been bias-adjusted by regional observational oceanic data as described in subsection **2.4.3**. In this  
337 case most models only use the bias-adjusted inputs and not the raw ones. Nevertheless the experiments  
338 are labeled as ‘de-biased’ sensitivity experiments to ensure a consistent naming across scales.  
339

## 340 **1.2 ISIMIP3b, group II: Climate-model based future impact model simulations with** 341 **constant 2015 direct human forcings**

342  
343 The ISIMIP3b, group II simulations comprise a set of future impact projections (2015-2100) using fixed  
344 levels of [DHFdirect human forcings](#) as considered in the historical simulations (‘2015soc’, ‘1850soc’, and  
345 ‘nat’) or reached at the end (2014) of the historical period in the ‘historical + histsoc’ runs (‘2015soc-from-  
346 histsoc’). These runs are described in the red cells of **Table 24**.  
347

348 **Pre-industrial reference simulations (picontrol + 2015soc, picontrol + 2015soc-from-histsoc, picontrol +**  
349 **1850soc, picontrol + nat; default):** These simulations are included into the ISIMIP3, group II part of the  
350 protocol to allow for the estimation of the effect of climate change by comparing the future impact  
351 projections to simulations assuming the same background DHF but pre-industrial levels of CRF (see  
352 description of baseline simulations in section **1.1**).  
353

354 **Future impact projections assuming SSP-RCP-based climate-related forcings starting from ‘historical +**  
355 **histsoc’ simulations (ssp126 + 2015soc-from-histsoc, ssp370 + 2015soc-from-histsoc, ssp585 + 2015soc-**  
356 **from-histsoc; default):** These runs are a continuation of the group I ‘historical + histsoc’ simulations  
357 assuming fixed 2015 [DHFdirect human forcings](#) for the future. Note that this experiment is different from  
358 the experiment with fixed 2015 DHF for the future starting from the ‘historical + 2015soc’ group I  
359 experiment (see description below).  
360

361 These experiments have been introduced to describe the impacts of different scenarios of changes in the  
362 climate-related systems on today’s natural systems and societies, i.e. assuming present day population  
363 levels and distributions, land use patterns, water, and agricultural management measures etc.. In many  
364 cases, the projected changes in natural and human systems can be interpreted as the pure effect of the  
365 prescribed changes in the climate-related systems. However, they could also partly result from lagged  
366 effects of the historical changes in DHFs (‘histsoc’), CRF (‘historical’), or natural temporal trends induced

367 e.g. by re-growth of forests. To be able to separate natural trends from the effects of changing CRFs, these  
368 simulations can be compared to reference impact simulations with pre-industrial [CRFclimate-related](#)  
369 [forcings](#) forced with the same [DHFdirect-human-forcings](#) ('picontrol + 2015soc-from-histsoc', see  
370 description in group I section).

371  
372 **Future impact projections assuming SSP-RCP-based climate-related forcings starting from historical**  
373 **simulations with constant 2015 direct human forcings (ssp126 + 2015soc, ssp370 + 2015soc, ssp585 +**  
374 **2015soc; default):** These experiments continue the 'historical + 2015soc' experiments from ISIMIP3b,  
375 group I using [DHFdirect-human-forcings](#) held constant at 2015 levels for the historical period. Although  
376 the DHF in the future period is identical to the future simulations described above, the difference in  
377 historical forcing may affect the impact simulations in the future period. These simulations are also  
378 considered first priority as some of the impact models may not be able to handle varying [DHFdirect-human](#)  
379 [forcings](#) and therefore can only perform these experiments. Models participating in the '2015soc-from-  
380 histsoc' experiments described above are also asked to complete the '2015soc' runs to generate an as  
381 large as possible ensemble of consistent impact model simulations.

382  
383 **Future impact projections assuming SSP-RCP-based climate-related forcings starting from historical**  
384 **simulations assuming constant 1850 direct human forcings (ssp126 + 1850soc, ssp370 + 1850soc, ssp585**  
385 **+ 1850soc; default):** These experiments continue the default 'historical + 1850soc' experiments  
386 considered in ISIMIP3b, group I. They are included to estimate the impact of changes in the climate-  
387 related systems conditional on 1850 levels of [DHFdirect-human-forcings](#) that can be compared to the  
388 impact conditional on today's levels of [DHFdirect-human-forcings](#) ('2015soc').

389  
390 **Future impact projections assuming SSP-RCP-based climate-related forcings starting from historical**  
391 **simulations assuming no direct human forcings (ssp126 + nat, ssp370 + nat, ssp585 + nat; default):** These  
392 experiments continue the default 'historical + nat' experiments in ISIMIP3b, group I. They are included to  
393 estimate the effect of changes in the climate-related systems (here climate change itself and increasing  
394 CO<sub>2</sub> concentrations) assuming no [DHFdirect-human-forcings](#).

395  
396 **CO<sub>2</sub> sensitivity simulations (ssp126 + 2015soc-from-histsoc, ssp370 + 2015soc-from-histsoc, ssp585 +**  
397 **2015soc-from-histsoc, ssp585 + 2015soc, ssp585 + 1850soc, ssp585 + nat; 2015co2):** To separate the  
398 effects of increasing atmospheric CO<sub>2</sub> concentrations from the effects of other changes in the climate-  
399 related systems, the ISIMIP3b protocol includes sensitivity experiments where atmospheric CO<sub>2</sub>  
400 concentrations are held constant at 2015 levels. For SSP1-2.6 and SSP3-7.0, they are only introduced as  
401 deviations from the default '2015soc-from-histsoc' experiments while for SSP5-8.5 the effect can also be  
402 quantified conditional on all levels of direct human influences considered in the previous experiments.

403 **Future lightning sensitivity simulations (ssp126 + 2015soc-from-histsoc, ssp370 + 2015soc-from-histsoc,**  
404 **ssp585 + 2015soc-from-histsoc; varlightning):** To study the effects of future changes in lightning flash  
405 rates as opposed to using a stationary lightning climatology, the ISIMIP3b protocol includes sensitivity  
406 experiments where future lightning flash rates change along the RCPs. The future lightning data sensitivity

407 experiment is introduced as a deviation from the default ‘2015soc-from-histsoc’ experiment and only for  
 408 one climate model (UK-ESM). This sensitivity experiment has been introduced for the fire sector.

409 **Climate sensitivity simulations under high levels of CO<sub>2</sub> (ssp126 + 2015soc-from-histsoc, ssp585co2):** To  
 410 study the effects of high atmospheric CO<sub>2</sub> concentration without accompanying changes in climate, the  
 411 ISIMIP3b protocol includes a sensitivity experiment where the atmospheric CO<sub>2</sub> concentration are  
 412 prescribed according to RCP8.5, while the other [CRF climate-related forcings](#), in particular the atmospheric  
 413 forcings are from SSP1-2.6. The future climate sensitivity experiment is introduced as a deviation from the  
 414 default ‘ssp126 + 2015soc-from-histsoc’ experiment. This sensitivity experiment has been introduced for  
 415 the peat sector.

416 **‘De-biased’ sensitivity simulations within the marine ecosystems and fisheries sector (FishMIP) with de-**  
 417 **biased oceanic forcings and no or 2015soc direct human forcings for reference simulations based on**  
 418 **pre-industrial oceanic forcing (picontrol + nat, picontrol + 2015soc-from-histsoc; de-biased) and the**  
 419 **associated simulations accounting for different levels of climate change (ssp126 + nat, ssp370 + nat,**  
 420 **ssp858 + nat, ssp126 + 2015soc-from-histsoc, ssp370 + 2015soc-from-histsoc, ssp585 + 2015soc-from-**  
 421 **histsoc):** These simulations represent the future extensions of the ‘de-biased’ group I simulations  
 422 described above. They are designed to test the dynamical bias-adjustment suggested for the global  
 423 oceanic forcings under different levels of climate change (ssp126, ssp370, ssp585). The regional impact  
 424 projections within the sector are also based on de-biased oceanic forcings and are therefore also labeled  
 425 as ‘de-biased’ sensitivity experiments to ensure a consistent labeling across scales.

426  
 427 [Table 2: ISIMIP3b climate-model based experiments. The table provides a comprehensive list of all](#)  
 428 [ISIMIP3b, group I \(grey\) and group II \(red\) experiments defined by the assumed climate-related forcings](#)  
 429 [\(CRF\) and direct human forcings \(DHF\). Here the climate-related forcings are only described by the climate](#)  
 430 [\(oceanic and atmospheric\) and CO<sub>2</sub> forcings as we do not provide coastal water levels yet.](#)

~~**Table 2: ISIMIP3b climate model based experiments.** The table provides a comprehensive list of all ISIMIP3b, group I (grey) and group II (red) experiments defined by the assumed climate-related forcings (CRF) and direct human forcings (DHF). Here the climate-related forcings are only described by the climate (oceanic and atmospheric) and CO<sub>2</sub> forcings as we do not provide coastal water levels yet.~~

## 2 Climate-related forcing data

### 2.1 Bias-adjusted and statistically downscaled atmospheric climate forcing

For ISIMIP3b we provide the daily atmospheric forcings for the same variables as in ISIMIP3a on the default 0.5° grid (see **Table 3**). These variables are from the output of CMIP6 climate model simulations, selected and processed as described below. We use the climate simulations from the piconrol (for pre-industrial conditions), historical (for historical conditions), ssp126, ssp370, and ssp585 (for future conditions under the scenarios SSP1-2.6, SSP3-7.0, and SSP5-8.5, respectively) CMIP6 experiments.

449  
450  
451  
452  
453

**Table 3:** Climate-related atmospheric forcing data provided within ISIMIP3b. The upper limits of [precipitation \(pr\)](#) and [snowfall \(prsn\)](#) correspond to 600 mm day-1 and 300 mm day-1, respectively, while the lower and upper limits of [Near-Surface Air Temperature \(tas\)](#), [Daily Maximum Near-Surface Air Temperature \(tasmax\)](#) and [Daily Minimum Near-Surface Air Temperature \(tasmin\)](#) correspond to -90°C and +70°C, respectively.

Variable	Variable specifier	Unit (maximum range, inner bounds if considered)	Resolution	Datasets
Near-Surface Relative Humidity	<b>hurs</b>	% ([1, 100], [0.01, 99.99])	0.5° grid, daily	Bias-adjusted and downscaled from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Near-Surface Specific Humidity	<b>huss</b>	kg kg-1 ([0.0000001, 0.1])	0.5° grid, daily	Derived from bias-adjusted and downscaled hurs, ps, and tas from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Precipitation (including snowfall)	<b>pr</b>	kg m-2 s-1 ([0, 600/86400], [0.1/86400, ∞])	0.5° grid, daily	Bias-adjusted and downscaled from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Snowfall	<b>prsn</b>	kg m-2 s-1 ([0, 300/86400])  Maximum range and inner bounds of unitless snowfall ratio (prsnratio = prsn/pr):  ([0,1], [0.0001,0.9999])	0.5° grid, daily	Derived from bias-adjusted and downscaled pr and prsnratio from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Surface Air Pressure	<b>ps</b>	Pa ([480, 110000])	0.5° grid, daily	Bias-adjusted and downscaled from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Surface Downwelling Longwave Radiation	<b>rlds</b>	W m-2 ([40, 600])	0.5° grid, daily	Bias-adjusted and downscaled from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and

				UKESM1-0-LL simulations generated for CMIP6.
Surface Downwelling Shortwave Radiation	<b>rsds</b>	W m <sup>-2</sup> ([0, 500])  Maximum range and inner bounds of normalized rsds used during bias adjustment: ([0,1], [0.0001, 0.9999])	0.5° grid, daily	Bias-adjusted and downscaled from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Near-Surface Wind Speed	<b>sfcwind</b>	m s <sup>-1</sup> ([0.1, 50], [0.01,∞[)	0.5° grid, daily	Bias-adjusted and downscaled from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Near-Surface Air Temperature	<b>tas</b>	K ([183.15, 343.15])	0.5° grid, daily	Bias-adjusted and downscaled from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Daily Maximum Near-Surface Air Temperature	<b>tasmax</b>	K ([183.15, 343.15])  Maximum range and inner bounds considered for tasrange: ([0.01, ∞[, [0.01,∞[)  Maximum range and inner bounds considered for unitless tasskew: ([0,1], [0.0001,0.9999])	0.5° grid, daily	Derived from bias-adjusted and downscaled tasrange = tasmax - tasmin and tasskew = (tas - tasmin) / (tasmax - tasmin) from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.
Daily Minimum Near-Surface Air Temperature	<b>tasmin</b>	K ([183.15, 343.15])  Maximum range and inner bounds considered for tasrange: ([0.01, ∞[, [0.01,∞[)  Maximum range and inner bounds considered for unitless	0.5° grid, daily	Derived from bias-adjusted and downscaled tasrange = tasmax - tasmin and tasskew = (tas - tasmin) / (tasmax - tasmin) from GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL simulations generated for CMIP6.

		tasskew: ([0,1], [0.0001,0.9999])		
--	--	--------------------------------------	--	--

454  
455 For the pre-industrial conditions, 500 years of piconrol output data are used and harmonised across  
456 [General Circulation Models \(GCMs\)](#) with respect to the time range they cover. This is possible because  
457 piconrol data only carry nominal year labels. We shift the GCM-specific piconrol time ranges listed in  
458 **Table 4** to 1601–2100. For the historical and future climate conditions, we provide input data for 1850–  
459 2014 and 2015–2100, respectively, in line with the time ranges covered by the corresponding CMIP6  
460 experiments. The common time axis is important as the use of the input data should be harmonised across  
461 all sectors. In particular, the year-by-year combination of the pre-industrial [CRFclimate-related forcing](#)  
462 with the historical [DHFdirect human forcing](#) should be done in the same way across all sectors and models.  
463

464 **Selection of climate models.** To limit the number of mandatory impact simulations and hence lower the  
465 barrier to participation in ISIMIP3b, we provide climate input data for only five selected CMIP6 climate  
466 models. The basic characteristics of the five GCMs are listed in **Table 4**. The models were selected based  
467 on data availability at the selection time (late 2019 to early 2020), performance in the historical period,  
468 structural independence, process representation and equilibrium climate sensitivity (ECS).  
469

470 To be included in ISIMIP3b, a GCM had to provide daily data for all variables listed in **Table 3** except for  
471 [near-surface specific humidity \(huss\)](#) (which was derived from [near-surface relative humidity \(hurs\)](#), [surface air](#)  
472 [pressure \(ps\)](#) and [near-surface air temperature \(tas\)](#), see below), ps if sea level pressure (psl) was available,  
473 so a proxy for ps could be computed based on psl and tas, and [near-surface wind speed \(sfcwind\)](#) if zonal  
474 and meridional near-surface wind components (uas, vas) were available, so a proxy for sfcwind could be  
475 computed based on uas and vas. Those daily data had to cover 500 piconrol years and all years of the  
476 historical, SSP1-2.6, SSP3-7.0, and SSP5-8.5. In addition, we favoured GCMs that provided the additional  
477 input data needed for the tropical cyclone modelling (**Table 5**) and the fisheries and marine ecosystems  
478 sector (FishMIP; **Table 10**).  
479

480 **Table 4:** Characteristics of CMIP6 climate models used in ISIMIP3b. Columns show (from left to right) the  
481 climate model acronym, the horizontal grid size (longitude x latitude) of the original atmospheric output  
482 data, the ensemble member used, the nominal time range covered by the piconrol data used, the  
483 [equilibriumeffective](#)equilibrium climate sensitivity (ECS) according to (Meehl et al., 2020), and the main  
484 model reference paper and the CMIP6 simulation data publications used. For definitions of climate model  
485 acronyms and modelling groups see (Durack, n.d.).

GCM	Grid size	Member	piconrol	ECS	References
GFDL-ESM4	288 x 180	r1i1p1f1	0001–0500	2.6°C	(Dunne et al., 2020; John et al., 2018; Krasting et al., 2018)
IPSL-CM6A-LR	144 x 143	r1i1p1f1	1870–2369	4.6°C	(Boucher et al., 2018, 2019, 2020)

MPI-ESM1-2-HR	384 x 192	r1i1p1f1	1850–2349	3.0°C	(Jungclaus et al., 2019; Mauritsen et al., 2019; Schupfner et al., 2019)
MRI-ESM2-0	320 x 160	r1i1p1f1	1850–2349	3.2°C	(Yukimoto, Kawai, et al., 2019; Yukimoto, Koshiro, et al., 2019a, 2019b)
UKESM1-0-LL	192 x 144	r1i1p1f2	1960–2459	5.3°C	(Good et al., 2019; Sellar et al., 2019; Tang et al., 2019)

486

487

488 According to a skill analysis (see **Figure 2**), the GCMs ACCESS-CM2, AWI-CM-1-1-MR, CESM2, CESM2-  
489 WACCM, CMCC-ESM2, EC-Earth3-AerChem, GFDL-CM4, GFDL-ESM4, HadGEM3-GC31-LL, HadGEM3-  
490 GC31-MM, MPI-ESM1-2-HR, MPI-ESM1-2-LR, MRI-ESM2-0, NorESM2-MM, SAM0-UNICON, TaiESM1, and  
491 UKESM1-0-LL perform relatively well in reproducing the main historically observed characteristics of the  
492 atmosphere. From that list, only GFDL-ESM4, MPI-ESM1-2-HR, MRI-ESM2-0, and UKESM1-0-LL provided  
493 all required daily data at the time of model selection. Another model that fulfilled all those data  
494 requirements and shows an average performance in the historical period is IPSL-CM6A-LR. These five  
495 GCMs were selected to be used in ISIMIP3b. With the exception of GFDL-ESM4, these models also provide  
496 the data needed for tropical cyclone modelling. GFDL-ESM4 is the model providing the most  
497 comprehensive oceanic bio-geochemical forcings for FishMIP while other models cover less and partly  
498 other oceanic variables (see **Table 816**). Three of the climate models (GFDL-ESM4, IPSL-CM6A-LR,  
499 UKESM1-0-LL) are successors of models already used in ISIMP2b and in the ISIMIP Fast Track.

500

**Figure 2:** Relative space-time root-mean-square deviation (RMSD) calculated from the climatological seasonal cycle of the CMIP6 historical simulations (1980–1999) compared to observational datasets, for various CMIP6 GCMs (columns) and climate variables (rows), similar to Fig. 6 of (Bock et al., 2020). A relative performance is displayed, with blue shading being better and red shading worse than the median RMSD of all model results of the CMIP6 ensemble. A diagonal split of a grid square shows the relative error with respect to the reference data set (lower right triangle) and an alternative data set (upper left triangle), as listed in Table 5 of (Bock et al., 2020). White boxes are used when data are not available for a given model and variable. Models selected for ISIMIP3b are highlighted in red. Variables are (from top to bottom): Surface Downwelling Shortwave Radiation (rsds), Surface Upwelling Shortwave Radiation (rsus), Surface Downwelling Longwave Radiation (rlds), Surface Upwelling Longwave Radiation (rlus), Soil Moisture (sm), Ambient Fine Aerosol Optical Depth at 550 nm (od550lt1aer), Ambient Aerosol Absorption Optical Thickness at 550 nm (abs550aer), Ambient Aerosol Optical Depth at 870 nm (od870aer), Ambient Aerosol Optical Thickness at 550 nm (od550aer), Shortwave Cloud Radiative Effect (swcre), Longwave Cloud Radiative Effect (lwcre), Top-of-Atmosphere Outgoing Shortwave Radiation (rsut), Top-of-Atmosphere Outgoing Longwave Radiation (rlut), Total Cloud Cover Percentage (clt), Precipitation (pr), Surface Temperature (ts), Near-Surface Air Temperature (tas), Specific Humidity at 400 hPa (hus400), Sea Level Pressure (psl), Geopotential Height at 500 hPa (zg500), Northward Wind at 200 hPa (va200), Northward Wind at 850 hPa (va850), Eastward Wind at 200 hPa (ua200), Eastward Wind at 850 hPa (ua850), Air Temperature at 200 hPa (ta200), and Air Temperature at 850 hPa (ta850). Produced with ESMValTool v2.0 (Andela et al., 2020b, 2020a; Righi et al., 2020).

The five GCMs are structurally independent in terms of their ocean and atmosphere model components. Furthermore, all of them have a coupled climate and carbon cycle and in some cases, fully interactive

524 chemistry and aerosol components. We favoured models that applied prognostic couplings between  
525 processes and model domains wherever possible to maximise the coverage of simulated feedbacks.

526  
527 The five GCMs provide a good representation of both the mean and the range of the full CMIP6 multi-  
528 model ensemble ECS. According to (Meehl et al., 2020), the CMIP6 multi-model mean ECS is 3.7°C, which  
529 is precisely met by the mean ECS of the five ISIMIP3b GCMs. The transient climate response (TCR) of 2.0°C  
530 is also precisely met. This provides an improvement over ISIMIP2b, in the sense of the selected GCM  
531 subset reflecting the statistics of the larger CMIP ensemble. In ~~ISIMIP2b~~ that case the mean ECS for the full  
532 CMIP5 was 3.2°C compared with a mean ECS of 3.72°C for the four ISMIP2b GCMs (see Table S1 and S2 in  
533 (Jägermeyr et al., 2021)). The ISIMIP3b ensemble includes three models with below-average ECS (GFDL-  
534 ESM4, MPI-ESM1-2-HR, MRI-ESM2-0) and two models with above-average ECS (IPSL-CM6A-LR, UKESM1-  
535 0-LL) (see **Table 412**). In line with their ECS values, we find GFDL-ESM4 and UKESM1-0-LL to project the  
536 weakest and strongest global warming, respectively, under any future scenario considered (see **Figure 3**).  
537 Under SSP5-8.5, the global mean near-surface temperature in 2100 is about 3°C larger in UKESM1-0-LL  
538 than in GFDL-ESM4. Under SSP1-2.6, the projections are about 1.5°C apart. The ensemble mean warming  
539 of the ISIMIP3b CMIP6 models is significantly higher than the warming of the ISIMIP2b CMIP5 models,  
540 across global land area by an average of 0.3°C, but over the main breadbasket cropland regions by more  
541 than 0.5°C between 1983–2013 and 2069–2099, under both SSP1-2.6 and SSP5-8.5 (Table S1 in (Jägermeyr  
542 et al., 2021)). This is in line with the higher median ECS in CMIP6 compared to CMIP5; indeed, some CMIP6  
543 models have an ECS above the assessed likely (2.5°C to 4°C) and very likely (2°C to 5°C) ranges in the IPCC's  
544 sixth assessment report (AR6) (Forster et al., 2021). **The reasons for these higher estimates of ECS are**  
545 **complex, with cloud feedback processes playing an important role** (Zelinka et al., 2020). **While the**  
546 **plausibility of the very high ECS estimates has been questioned, recent studies indicate CMIP6 models**  
547 **with high ECS tend to simulate cloud properties better than low ECS models** (Bock & Lauer, 2024); **also,**  
548 **unaccounted natural variability may have biased the IPCC's assessed ranges somewhat low** (Liang et al.,  
549 2024; Watanabe et al., 2024)(Liang et al., 2024; Watanabe et al., 2024).;

550  
551 **The ISIMIP3b ensemble reflects the spread in ECS of the overall CMIP6 ensemble, with two models above**  
552 **the AR6 likely range and one of these (UKESM1-0-LL) above the very likely range. The strong warming**  
553 **response of these models should be kept in mind when conducting ISIMIP3b-based impacts studies.**  
554 **However, depending on the region and variable of interest, the high ECS does not necessarily have any**  
555 **bearing on the magnitude or realism of projected regional impacts, and any further selection of models**  
556 **should not be based solely on ECS but on the models' suitability for the impacts variables in question**  
557 **(Swaminathan et al., 2024)(Swaminathan et al., 2024). In many applications, results can be harmonized**  
558 **by describing the simulated impacts in terms of global mean temperature changes instead of time for the**  
559 **different emission scenarios.**

**Figure 3:** Time series of annual global mean near-surface temperature change relative to pre-industrial levels (1601–1849 average) as simulated with GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0 and UKESM1-0-LL (from top to bottom). Colour coding indicates the underlying CMIP6 experiments (grey: pre-industrial control, black: historical, blue: SSP1-2.6, light red: SSP3-7.0, dark red: SSP5-8.5) with corresponding time periods given at the top. Numbers to the right of the plot represent end-of-century warming levels under the different future

scenarios, expressed as the global multi-year mean near-surface temperature change from 1601–1849 to 2070–2100.

**Bias adjustment and statistical downscaling.** To make the GCM-based climate forcing usable for the impact modellers we apply a bias adjustment ensuring that the GCM simulations match the observed distribution of climate data over the historical reference period (1979–2014). In addition to the bias adjustment a statistical downscaling to our standard 0.5° grid is included in the pre-processing of the surface and near-surface atmospheric variables (see **Table 311**). The method used for the bias adjustment and statistical downscaling (BASD) in ISIMIP3b is version 2.5 of ISIMIP3BASD (Lange, 2019b, 2021a).

ISIMP3BASD has several advantages compared to the method used for bias adjustment and statistical downscaling in ISIMIP2b (Frieler et al., 2017; Lange, 2017, 2018). First, it clearly separates the adjustment of biases in climate model output at 1° or 2° resolution, whatever is closest to the original output data, from the statistical downscaling to the target resolution of 0.5°. Compared to ISIMIP2b, where climate model output was first spatially interpolated to the target resolution and then bias-adjusted, the new approach avoids the associated underestimation of ~~improves~~ the spatial variability at the target resolution (Lange, 2019b). Second, the new quantile mapping method preserves trends in each quantile of the distribution of the daily data and adjusts biases in distribution quantiles of the daily data more accurately than the ISIMIP2b bias adjustment methods (Lange, 2019b).

For trend preservation, we first produce pseudo-future observations by shifting the historically observed daily data by the simulated future climate change. Here, the signal of climate change is the difference or the ratio between the inverse empirical cumulative distribution function of the historical period and the respective distribution functions of each 36-year period of the future. Using the difference ensures additive trend preservation and using the ratio ensures multiplicative trend preservation under bias adjustment. We apply additive trend preservation for near-surface air temperature (tas), sea level pressure (psl, see **Table 36**), and surface downwelling longwave radiation (rlds). We apply primarily multiplicative trend preservation for precipitation including snowfall (pr), near-surface wind speed (sfcWind), and the range (tasrange = tasmax - tasmin) between the daily maximum and minimum near-surface air temperatures (tasmax and tasmin, respectively) that can transition smoothly to additive trend preservation for data with large negative biases in the historical period (Lange, 2019b). In a second step, the future simulations are mapped onto the pseudo-future observations by quantile mapping. Both steps, the generation of the pseudo future observations and the quantile mapping of the future simulations onto the pseudo observations, are applied for each day of the year separately. The distributions include data from the 31 days around the considered day and all years of the reference or future period, respectively. This means a sample size of 31x36 values for each day of the year. Through this approach the bias adjustment implicitly also adjusts the multi-year mean annual cycle and a mix of year-to-year and day-to-day variability (Haerter et al., 2011).

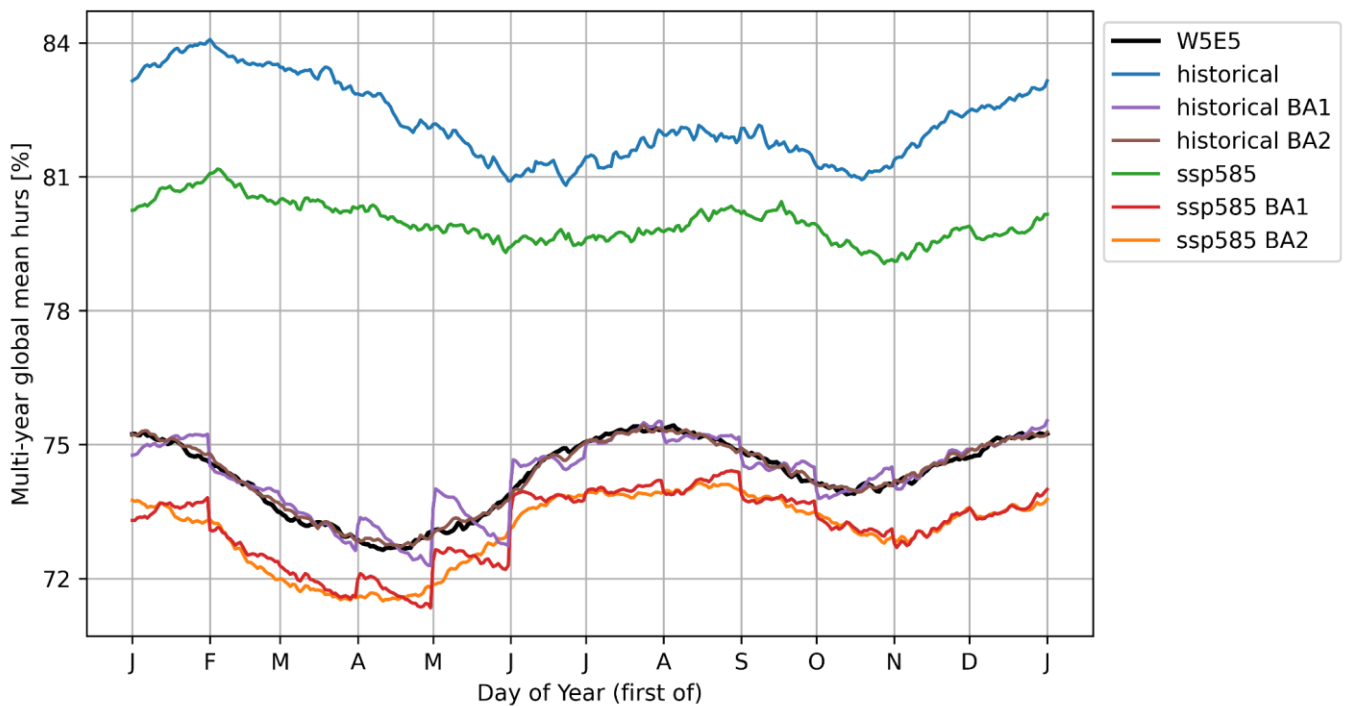

In addition, the method adjusts the frequency of daily data falling outside of the inner bounds specified in **Table 311** (e.g. the dry day frequency, i.e. the number of days with precipitation below 0.1 mm day<sup>-1</sup>).

Four variables were adjusted and downscaled indirectly: near-surface specific humidity (huss) was derived from adjusted and downscaled near-surface relative humidity (hurs), surface air pressure (ps), and near-surface air temperature (tas) using the equations of (Buck, 1981) as described in (Weedon et al., 2010), snowfall (prsn) was derived from adjusted and downscaled precipitation including snow (pr) and the snowfall ratio (prsnratio = prsn / pr), and daily maximum and daily minimum near-surface air temperatures (tasmax and tasmin, respectively) were derived from adjusted and downscaled tas, and the tasrange = tasmax - tasmin and skewness of the daily temperature cycle tasskew = (tas - tasmin) / (tasmax - tasmin).

The basic characteristics of ISIMIP3BASD (version 1.0) are described in (Lange, 2019b). However, the method finally used to generate the forcing data now provided within ISIMIP3b (ISIMIP3BASD version 2.5) deviates from the original version in some aspects. In the following we describe the most important updates of the procedure relative to the one described in (Lange, 2019b). For a complete list of differences between the two versions of the BASD method and the full history of which feature was added in which update, see the CHANGELOG included in the archive of code version 2.5 (Lange, 2021a).

In (Lange, 2019b) the bias-adjustment was applied on a monthly basis, i.e. the pseudo-future observations and the quantile mapping described above was applied to all daily January data, February data and so forth. This approach can introduce discontinuities at the transition from one month to another (see **Figure 4**). That is why for ISIMIP3b the adjustment is done in the running window mode with steps of one day and a window width of 31 days as described above. This approach resolves the discontinuity issue (see **Figure 4**), as suggested by (Thiemeßl et al., 2012); (Thrasher et al., 2012); (Gennaretti et al., 2015); and (Grenier, 2018).

633

634

635 Figure 4: Global multi-year daily mean near-surface relative humidity for UKESM1-0-LL historical (1979-  
 636 2014) and SSP5-8.5 (2065-2100), with uncorrected historical simulated data in blue, uncorrected  
 637 future simulated data in green, historical bias-adjusted data in purple and brown, future bias-adjusted data in red and  
 638 orange, and observational reference data in black. The bias is effectively reduced throughout all days of the year  
 639 (brown line closely matching the black line) when a smooth annual cycle is produced if ISIMIP3BASD v2.5 is applied  
 640 in running-window mode in steps of one day (brown and orange, BA2). In contrast, a month-by-month application,  
 641 which was the only option in ISIMIP3BASD v1.0, generates discontinuities at each turn of the month (purple and  
 642 red, BA1).

643

644 Since ps, rlds and tas can show significant trends within the 36-year training and application periods  
 645 ISIMIP3BASD v1.0 includes a detrending of these variables within these intervals before the pseudo future  
 646 observations and the transfer functions are estimated and applied. Afterwards the trend is added back  
 647 again. This is done to prevent the confusion of trends with interannual variability during quantile mapping

(Lange, 2019b; Maraun, 2013). In contrast to v1.0, in v2.5, applied to generate the ISIMIP3b forcings data, the detrending is only applied if the trend is significantly different from zero at the 5% level.

We also changed the method used to generate future pseudo-observations of bounded variables (equations (8) and (9) of (Lange, 2019b)), in order to stabilise results in some edge cases. If, e.g., the historically observed relative dry-day frequency was 0.0 while the simulated frequency was 0.8 for the historical period and 0.9 for some future period, then, according to equation (9) of (Lange, 2019b), the future pseudo-observed frequency would be equal to  $1 - (1 - 0.0)(1 - 0.9)/(1 - 0.8) = 0.5$ . As this is considered unrealistic we apply a revised version of equation (9) of (Lange, 2019b) that reads

$$P^{obs}_{fut} = \begin{cases} P^{sim}_{fut} & \text{if } P^{sim}_{hist} = P^{obs}_{hist}, \\ 0 + (P^{obs}_{hist} - 0)(P^{sim}_{fut} - 0)/(P^{sim}_{hist} - 0) & \text{if } P^{sim}_{fut} \leq P^{sim}_{hist} > P^{obs}_{hist}, \\ 1 - (1 - P^{obs}_{hist})(1 - P^{sim}_{fut})/(1 - P^{sim}_{hist}) & \text{if } P^{sim}_{fut} \geq P^{sim}_{hist} < P^{obs}_{hist}, \\ P^{obs}_{hist} + P^{sim}_{fut} - P^{sim}_{hist} & \text{otherwise.} \end{cases} \quad (1)$$

In this revised relation, the otherwise case applies if  $P^{sim}_{fut} < P^{sim}_{hist} < P^{obs}_{hist}$  or  $P^{sim}_{fut} > P^{sim}_{hist} > P^{obs}_{hist}$ . Hence it applies to the aforementioned edge case, where it produces a less extreme future pseudo-observed relative frequency of  $0.0 + 0.9 - 0.8 = 0.1$ . Equation (8) of (Lange, 2019b) was revised analogously to equation (9).

Furthermore, we refined the method used to generate future pseudo-observations (step 5 of the bias adjustment algorithm of (Lange, 2019b)) for all variables with at least one bound: In v1.0, the future pseudo observations were generated by transferring simulated trends in all distribution quantiles to the observational reference data. That included trends in, e.g., precipitation quantiles below the wet-day threshold. However, in some cases, the trend transfer turned many dry days into wet days, with a profound impact on the shape of the distribution of future pseudo-observed wet-day precipitation. As a result, simulated trends in wet-day precipitation intensity were not well preserved. In v2.5, trend transfers are restricted to values within threshold. This particularly improves the preservation of trends in wet-day precipitation intensities.

We also modified the bias adjustment method for Near-Surface Relative Humidity (hurs) because ISIMIP3BASD v1.0 turned out to produce unrealistic distributions of hurs under climate change if there are too many cases of supersaturation ( $hurs \geq 100\%$ ) in the simulated data. This is the case for several of the CMIP6 GCMs selected for ISIMIP3b, particularly in high-latitude winter: While no supersaturations are found in the observational reference data, the GCM simulates many supersaturations in the historical reference period and even more so in a future period, under SSP5-8.5 (see **Figure 5**). ISIMIP3BASD v1.0 preserves this projected trend and hence produces future bias-adjusted hurs data with many supersaturations. In v2.5, this trend is no longer preserved. Instead, the supersaturation probability is fixed at the observed level, which is zero or very close to zero in all seasons and grid cells for W5E5. Future

688 pseudo observations of hurs are generated by applying the revised (see above) equation (8) of (Lange,  
 689 2019b) to all hurs values after capping them at 100%. The new approach was motivated by findings from  
 690 (Ruosteenoja et al., 2017, 2018). They analysed hurs data from CMIP5 and showed that (i)  
 691 supersaturations in those data are mostly spurious, resulting from, e.g., inconsistencies in the  
 692 interpolation of temperature and specific humidity to the near-surface level, and (ii) climatological mean  
 693 value trends of hurs become more consistent with trends in relative humidity from the lowest model level  
 694 if hurs is capped at 100% before trends are calculated.

696  
 697  
 698 **Figure 5:** Empirical cumulative distribution functions of near-surface relative humidity in high-latitude winter  
 699 (November, 66.5°N, 133.5°E) for GFDL-ESM4 historical (1979-2014) and SSP5-8.5 (2065-2100), with historical  
 700 simulated data in blue, future simulated data in green, future bias-adjusted data in red and orange, and  
 701 observational reference data in black. The simulated climate change signal is well preserved with ISIMIP3BASD v2.5  
 702 using a fixed supersaturation (hurs  $\geq 100\%$ ) probability and equation (1) applied to all hurs values after capping  
 703 them at 100% to generate future pseudo observations (orange, BA2). In contrast, the simulated climate change  
 704 signal is not well preserved if the supersaturation probability is allowed to change and equations (8) and (9) of  
 705 (Lange, 2019b) are used to generate future pseudo observations of hurs (red, BA1).

706  
 707 In addition, while ISIMIP3BASD v1.0 applies parametric quantile mapping to all climate variables, we used  
 708 a nonparametric approach for the bias adjustment of near-surface relative humidity (hurs), the snowfall  
 709 ratio (prsnratio), surface downwelling shortwave radiation (rsds), and the skewness of the daily  
 710 temperature (tasskew) since the parametric quantile mapping method previously used for those variables  
 711 suffered from occasionally unstable beta distribution fits.

712  
 713 Moreover, the parametric quantile mapping described in (Lange, 2019b) does not only adjust biases in  
 714 quantiles of the simulated daily data but also adjusts biases in the likelihood of individual events, as in  
 715 (Switanek et al., 2017). To avoid overfitting artifacts we did not adjust event likelihoods for ISIMIP3b.

717 Finally, the diurnal temperature range (*tasrange*) was ultimately bias-adjusted using a Weibull  
 718 distribution, not a Rice distribution as described in (Lange, 2019b) because the Weibull distribution fits  
 719 the data better in most cases, in particular in the upper tail.

720  
 721 For further details of the application of ISIMIP3BASD v2.5 for ISIMIP3b, including the exact Python  
 722 commands and application periods used per CMIP6 experiment, see the ISIMIP3b bias adjustment fact  
 723 sheet (Lange, 2021b).

724  
 725 In addition, we use a new observational target dataset. Instead of using the EWEMBI dataset (E2OBS,  
 726 WFDEI and ERAI data merged and bias-corrected for ISIMIP; (Lange, 2019a) in ISIMIP3b we adjust the  
 727 climate forcing data to version 2.0 of the W5E5 dataset (WFDE5 over land merged with ERA5 over the  
 728 ocean; (Lange et al., 2021). The data cover the entire globe at 0.5° horizontal and daily temporal resolution  
 729 from 1979 to 2019. W5E5 v2.0 is derived by applying version 2.0 of the WATCH Forcing Data methodology  
 730 (WFDE5; (Cucchi et al., 2020) to ERA5 reanalysis data (Hersbach et al., 2020) and precipitation data from  
 731 version 2.3 of the Global Precipitation Climatology Project (GPCP; (Adler et al., 2003)).

732  
 733 The statistical downscaling method did not change between v1.0 and v2.5 of ISIMIP3BASD, i.e. for  
 734 ISIMIP3b we use the approach described (Lange, 2019b). This method adds the spatiotemporal variability  
 735 that is missing at the low spatial resolution at which the bias adjustment is done (1° or 2°, depending on  
 736 the GCM), compared to the target resolution of the downscaling (0.5°). The method is a modified version  
 737 of the MBCn algorithm from (Cannon, 2018), which in turn is a stochastic, multivariate, non-parametric  
 738 quantile mapping method. We use it to transfer the statistical relationship between low-resolution and  
 739 high-resolution W5E5 data to the GCM output that was previously bias-adjusted using low-resolution  
 740 W5E5 data. In comparison to the approach used in ISIMIP2b (a spatial interpolation to the target  
 741 resolution followed by a bias adjustment at that resolution), the approach used in ISIMIP3b is less prone  
 742 to inflate temporal variability and deflate spatial variability, i.e. the ISIMIP3b approach produces more  
 743 realistic spatiotemporal variability patterns at the target resolution (Lange, 2019b).

## 745 2.2 Tropical cyclones

746  
 747 **Table 5:** Information about tropical cyclone tracks and windfields provided as climate-related forcing data  
 748 within ISIMIP3b.

Variable	Variable specifier	Unit	Resolution	Datasets
Time associated with a given location of the storm centre	<b>time</b>	hours since 1950-01-01 00:00	along-track, 2-hourly (MIT model) 6-hourly (CHAZ model)	MIT (Emanuel et al., 2008) and -CHAZ (Lee et al., 2018)
Latitudinal coordinate of storm centre	<b>lat</b>	degrees north	along-track, 2-hourly (MIT model) 6-hourly (CHAZ model)	MIT (Emanuel et al., 2008) and -CHAZ (Lee et al., 2018)

Longitudinal coordinate of storm centre	<b>lon</b>	degrees east	along-track, 2-hourly (MIT model) 6-hourly (CHAZ model)	MIT (Emanuel et al., 2008) and -CHAZ (Lee et al., 2018)

Radius of maximum wind speeds	<b>rmw</b>	km	along-track, 2-hourly	MIT (Emanuel et al., 2008)
Wind speed on the 850 hPa pressure level	<b>ua850</b> <b>va850</b>	<del>ms<sup>-1</sup>knots (MIT model), ms<sup>-1</sup> (CHAZ model)</del>	along-track, 2-hourly (MIT model) 6-hourly (CHAZ model)	MIT (Emanuel et al., 2008) and -CHAZ (Lee et al., 2018)
Temperature on the 600 hPa pressure level	<b>ta600</b>	K	along-track, 2-hourly (MIT model) 6-hourly (CHAZ model)	MIT (Emanuel et al., 2008) and -CHAZ (Lee et al., 2018)
Frequency of TC occurrence	<b>freqyear</b>	count per year	annual	MIT (Emanuel et al., 2008)
Gridded lifetime maximum 1-minute sustained wind speed	<b>windlifetimemax</b>	ms <sup>-1</sup>	Per storm on a 300 arc-seconds (~10 km) grid	Wind fields calculated with Holland and Emanuel-Rotunno wind profiles (Holland, 1980, 2008) for <del>MIT both sets of synthetic tracks (CHAZ and MIT)</del>
Maximum 24-hourly rainfall total during the whole storm duration	<b>maxrain</b>	mm	per storm on a 300 arc-seconds (~10 km) grid	Maximum 24-hourly rainfall (Zhu et al., 2013) calculated for Holland and Emanuel-Rotunno wind profiles for <del>MIT both sets of synthetic tracks (CHAZ and MIT)</del>

749

750 We provide large ensembles of potential realisations of TC tracks and intensities that are consistent with  
751 the large-scale atmospheric and oceanic conditions simulated by ~~four of the five~~ the 5 ISIMIP3b GCMs (see  
752 **Table 64**) and for a selection of scenarios considered in ISIMIP3b (see **Table 1**). ~~We provide gridded wind~~  
753 ~~(maximum 1-minute sustained wind speeds during the whole duration of the TC) and rainfall (maximum~~  
754 ~~24 hourly amounts of rain during the whole duration of the TC) fields at a spatial resolution of 300 arc-~~  
755 ~~seconds (approximately 10 km) by the same approaches also applied to the historically observed tracks~~  
756 ~~(Frieler et al., 2024a), section 3.2).~~

The tracks are generated by two different statistical-dynamical approaches, the MIT approach and the CHAZ approach detailed below. ~~that, forced by data from the ISIMIP3b GCMs listed in data (see Table 64), these allow generating large ensembles of potential realisations of numerous a large number of synthetic storms.~~ For the MIT, approach, we provide gridded wind (maximum 1-minute sustained wind speeds during the whole duration of the TC) and rainfall (maximum 24-hourly amounts of rain during the whole duration of the TC) fields at a spatial resolution of 300 arc-seconds (approximately 10 km) using the same approaches also applied to the historically observed tracks ((Frieler et al., 2024), section 3.2).

Both methods to generate the TC tracks consist of a genesis, a track, and an intensity module:

~~The MIT approach.~~ Within MIT (Emanuel et al., 2008), the time-evolving state of the atmosphere and ocean surface given by the GCMs is randomly (uniformly distributed in time and space) seeded by weak proto-cyclones (genesis module). The seed disturbances are assumed to move with the GCM-provided large-scale flow in which they are embedded, plus a westward and poleward component owing to planetary curvature and rotation (track module). Their intensity is calculated using the Coupled Hurricane Intensity Prediction System (CHIPS; (Emanuel et al., 2004), a simple axisymmetric hurricane model coupled to a reduced upper ocean model to account for the effects of upper ocean mixing of cold water to the surface (intensity module). Applied to the synthetically generated tracks, this model simulates which of the seeded proto-cyclones develop into TCs, reaching maximum 1-minute sustained wind speeds of at least 35 knots, or dissipate due to unfavourable environments. The probabilistic seeding of proto-cyclones is repeated until the desired number of storms per year is reached (in our case, 1500). For each year, the share of proto-cyclones that dissipated in the process is used to derive an estimate of annual TC occurrences (**freqyear**). Extensive comparisons to historical events (Emanuel et al., 2008) have revealed that the statistical properties of the simulated events are consistent with historical TC genesis.

~~1500 tracks were generated globally and F~~for each year of the ISIMIP3b period 1850—2100 (except for GFDL-ESM4, where tracks were only generated for 1850-2014 and 2061-2100, and MRI-ESM2-0 for 1950-2100, see **Table 1**), 1500 tracks were generated, globally. Depending on the application, a simple subsampling (Meiler et al., 2022) or a more advanced bias-correction and emulation procedure (Geiger et al., 2021) might be necessary to extract properly-sized sets of potential realisations from the MIT ensembles.

The “ISIMIP3b tropical cyclone tracks MIT” dataset shall only be used for noncommercial purposes, including teaching and research at universities, colleges and other educational institutions, research at non-profit research institutions, and personal non-profit purposes. It is accessible through the ISIMIP data portal after agreeing to the corresponding license.

For using the tracks for commercial purposes, including but not restricted to consulting activities, software or data products, and a commercial entity participating in research projects, please contact Kerry Emanuel (MIT, email: emanuel@mit.edu) for an appropriate license.

~~The MIT track data shall be used for non-commercial research or academic purposes only. Data can be made available by the ISIMIP team upon written consent by Kerry Emanuel (MIT, email: emanuel@mit.edu).~~

795 ~~The~~ **CHAZ approach.** CHAZ (Lee et al., 2018) seed disturbances are also initialised randomly, but, in  
796 contrast to the MIT model, the global seeding rate and the local probabilities are derived from two  
797 versions of a TC genesis index (TCGI, (Tippett et al., 2011) (genesis module) and intended to represent the  
798 environmental conditions instead of being adjusted to produce a prescribed number of TCs. It is noted  
799 that CHAZ’s projection of global and basin-wide TC annual frequency is sensitive to the choice of the  
800 particular variable used to represent moisture in its genesis module. Simulations using column relative  
801 humidity (CRH) as the moisture variable tend to project an overall increase in global TC frequency, while  
802 those using saturation deficit (SD) show a decrease (Camargo et al., 2014), (Lee et al., 2020). Both  
803 parameters describe how far the atmosphere is from saturation, and they have very similar spatial  
804 patterns in the present climate, so historical data cannot be used to determine which variable is the best  
805 choice to represent the climate. These two configurations reflect the uncertainty of TC frequency  
806 projections (Sobel et al., 2021). Here we provide CHAZ downscaling using both choices of moisture  
807 variable to account for this uncertainty.

808 Similar to MIT, CHAZ then moves the synthetic storms by advection of the environmental steering flow  
809 plus a beta drift (track module). The evolution of synthetic storm intensity is calculated using the  
810 surrounding atmospheric conditions through an empirical multiple linear regression model plus a  
811 stochastic component (intensity module, (Lee et al., 2015, 2016)). The stochastic component accounts for  
812 internal storm dynamics that do not depend explicitly on the environment. While, in MIT, TC occurrence  
813 frequency is provided as an additional variable, in CHAZ, this information is implicitly contained in the  
814 number of TCs that were seeded by the genesis module and that reached TC strength according to the  
815 intensity module.

816 For ISIMIP3b, 20 different CHAZ realisations of the genesis and subsequent tracks are generated with 40  
817 ensemble members each from the intensity module for the historical period and for all RCP-SSP  
818 combinations considered within ISIMIP3b. For each of the 20 realisations, we compute wind and rain fields  
819 for the first ensemble member from the intensity ensemble. The design of 20 realisations allows CHAZ to  
820 generate similar numbers (~1800) of synthetic storms per year per GCM as the MIT models over the  
821 historical period. The exact number of storms per year in CHAZ varies by GCM, by scenario, by the choice  
822 of humidity variables in CHAZ’s genesis component (Lee et al., 2020). On average, CHAZ generates 1817,  
823 1802, 1820, 1810, 1842 storms per year for GFDL-ESM4, IPSL-CM6A-LR, MPI-ESM1-2-HR, MRI-ESM2-0,  
824 and UKESM1-0-LL, respectively. The CHAZ model has been shown to capture the statistical properties of  
825 the observed storms when forced by a global reanalysis data (Lee et al., 2018). Its CMIP6 downscaling  
826 results are reported in (Fosu et al., 2024). (Sobel et al., 2019) used both models to study cyclone risk at  
827 Mumbai, India and showed that MIT and CHAZ generate comparable return periods (frequency of  
828 exceedance) of maximum wind speeds at landfall. However, a frequency bias-correction might still be  
829 necessary, depending on the application (Meiler et al., 2022).

830 The “ISIMIP3b tropical cyclone tracks (CHAZ)” dataset shall only be used for non-commercial purposes,  
831 including teaching and research at universities, colleges and other educational institutions, research at  
832 non-profit research institutions, and personal non-profit purposes. It is accessible through the ISIMIP data  
833 portal after agreeing to the corresponding license.

834 For using the tracks for commercial purposes, including but not restricted to consulting activities, software  
 835 or data products, and a commercial entity participating in research projects, please contact Chia-Ying Lee

## 845 2.3 Coastal water levels

846

847 **Table 7:** Coastal water level specifications

Variable	Variable specifier	Unit	Resolution	Datasets
Coastal water levels	<b>cwl</b>	m	custom coastal grid  Hourly or daily maxima	planned

848

849

We do not yet provide coastal water levels as forcing data for ISIMIP3b. However, we plan to generate time series of coastal water levels from 1900 to 2100 at hourly resolution or for daily maxima. The data set and method will be described in a separate manuscript. Similar to the hourly water level dataset of ISIMIP3a (see section 3.3 of (Frieler et al., 2024) and (Treu et al., 2023)), we will combine longer-term annual sea level change with estimates of short-term coastal water level variation. Concerning the long-term sea level change component, we ~~go beyond will further develop~~ the ISIMIP2b approach (Frieler et al., 2017) and use tide gauge, satellite, vertical land motion and global climate model data to constrain a model with observations and IPCC AR6 projections in a Bayesian setting building on (Perrette & Mengel, 2025). ~~The (Perrette & Mengel, 2025) model Modelled global contributions from ice sheets and fingerprints are translated to regional sea level rise via fingerprints. A new aspect is that we include an estimation of vertical land motion to provide relative coastal water levels instead of geocentric coastal water levels. The~~ model allows for smooth projections of relative sea level from observational time series collected at tide gauge stations with an explicit representation of the different components of sea level rise (Perrette & Mengel, submitted 2024). To become usable for ISIMIP3 ~~the approach we will a) extend the approach will be extended~~ to all coastlines and b) use GCM output directly for the global thermosteric and local sterodynamic components (Gregory et al., 2019) of sea level rise, which are modeled by the GCMs. Extension to all coastlines is possible for the ice sheet, glacier and sterodynamic components as they rely on spatial fingerprints or GCM output. Processes driving vertical land motion that are not related to large scale climate processes are however more difficult to model. They are estimated from data as residual vertical land motion in (Perrette & Mengel, 2025). As we do not have data at all coastlines we will extrapolate in time and space the historical rates from tide gauge sites or apply zero rates for this component. Using the explicit component structure of the model, we replace the global thermosteric and the local sterodynamic parts by the output from ISIMIP GCMs. To that end, we reference the gridded sterodynamic simulation data with observations of that component so that they smoothly emerge from the historical period. We do not adjust variability or trends of the GCM data. The method will provide relative sea level projections (including vertical land motion), which can be directly used in coastal impact studies. We plan to estimate the short-term coastal water level variation by a machine-learning approach that is trained to reproduce simulations of the Global TideSurge and SurgeTide Model (GTSM) ~~model~~ driven by ERA5 reanalysis data (Muis et al., 2020) or simulations from HighResMIP (Muis et al., 2023). We are currently testing the dependency of the short-term water level variation on available atmospheric information at GCM resolution. If the predictive power is high enough we will use the findings to provide computationally efficient water level projections specific for the ISIMIP GCMs.

## 2.4 Ocean data

In the default experiments, the ocean variables provided by the GCMs are not subject to bias-adjustment, unlike the atmospheric forcing data (section 2.4.1). This is due to the absence of a comprehensive global observational oceanic dataset to serve as a reference for the adjustment.

However, in order to mitigate potential biases in global impact model simulations stemming from biases in raw oceanic forcing data, we provide a de-biased version to be used in a sensitivity experiment (see **Table 2**). They will be derived from an ocean-biogeochemistry model forced by bias-adjusted monthly

891 atmospheric surface flux data from four of the five ISIMIP3b GCMs. The approach preserves the monthly  
 892 variability of the underlying GCM while the daily variability is added from an independent simulation (see  
 893 section **2.4.2**).

894 For the regional impact model simulations, observational data for individual variables have either been  
 895 applied directly (if the required forcing was observed) to rectify biases in regional oceanic forcings by the  
 896 delta method or have first been translated into the required forcing variable by model simulations (see  
 897 section **2.4.3**). In the delta approach absolute simulated deviations from reference levels are added to the  
 898 observed reference levels. The regional bias-adjustment is independent from the generation of the global  
 899 de-biased forcing data.

900 In order to gauge the effects of these adjustments on the corresponding impact simulations, the protocol  
 901 includes sensitivity experiments (**'de-biased'**) grounded on these adjusted [CRFclimate-related forcings](#)  
 902 (see **Table 2**). The comparison of associated impact simulation to the default ones is expected to provide  
 903 valuable insights into the effects of potential biases in the [CRFclimate-related forcings](#). The 'de-biased'  
 904 experiments are considered a starting point to develop methods to bias-adjust the oceanic forcings in  
 905 further ISIMIP simulation rounds and make these simulations the default ones. Following the ISIMIP  
 906 'consistency framing' the bias-adjustment should also preserve the daily variability of the original GCM  
 907 simulations to allow for a cross-sectoral integration on daily time scale. .

908 **2.4.1 Raw data without bias adjustment (default experiment)**

909 In ISIMIP3b, a set of physical and biogeochemical ocean variables nearly identical to that in ISIMIP3a is  
 910 provided (see section **3.4**, **Table 8** of (Frieler et al., 2023) and **Table 8** below). These variables are obtained  
 911 from the CMIP6 GCMs, which also supply the atmospheric forcing for ISIMIP3b, except for MRI-ESM2-0,  
 912 which lacks bio-geochemical variables. In other models, only certain individual variables are missing (see  
 913 **Table 8**). Obtaining both atmospheric and oceanic variables from the same set of GCMs ensures  
 914 consistency between the fisheries and marine ecosystems sector and other ISIMIP sectors. The available  
 915 variables in ISIMIP3b are interpolated from the native grids of the ocean models to a regular 1° grid. This  
 916 resolution is comparatively lower than that of the ISIMIP3a ocean input data due to the generally reduced  
 917 native resolution of CMIP6 GCM simulations compared to the ocean model used to generate the oceanic  
 918 forcings based on observational atmospheric forcings for ISIMIP3a.

919  
 920 **Table 8:** Oceanic climate-related forcing data provided within ISIMIP3b. Variables with suffixes -bot, -surf,  
 921 and -vint were obtained from the seafloor, the top layer of the ocean, and vertical integration,  
 922 respectively.

Variable	Variable specifier	Unit	Resolution	Datasets

GCMs have been shown to have limitations in accurately representing various aspects of the present climate system (Eyring et al., 2023), (Séférian et al., 2020), that are also expected to affect regional physical and biogeochemical oceanic projections (Li et al., 2016), (Tagliabue et al., 2021). In particular, biases in sea-surface temperature (SST, variable 'tos') and nutricline as well as thermocline depth influence oceanic primary productivity, which in turn has major influence on various marine ecosystem processes. Thus, reducing the substantial biases in GCMs' ocean variables through bias-adjustment is desirable. Typically, for bias-adjustment of atmospheric variables, statistical approaches are used where a transfer function is trained to map the simulated historical distribution of the relevant variables to the observed distribution and then applied to future simulations. Yet for oceanic variables, the scarcity of comprehensive sub-surface observational data globally does not allow for a similar, direct adjustment of the relevant variables. However, standalone ocean-biogeochemistry simulations, when driven by observation-based atmospheric reanalysis data, have been demonstrated to considerably alleviate SST-related biases and typically provide satisfactory simulations of the physical ocean and marine biogeochemistry for the historical period (e.g. (Tsuji et al., 2020), (Barrier et al., 2023)). Thus, an alternative process-oriented bias-adjustment approach has been developed that relies on a comprehensive ocean-biogeochemistry model that is forced by bias-adjusted atmospheric forcings. The adjustment of the ISIMIP3b oceanic forcings builds on such a dynamical de-biasing approach (Lengaigne et al., 2025), which relies on conducting forced oceanic simulations using the NEMO-PISCES physical-biogeochemical ocean model (Madec, 2015), which is the oceanic component of the IPSL-CM6A-LR climate model. The ocean model needs to be forced with high-frequency (3-hourly) surface momentum, heat and freshwater fluxes. Since from the CMIP6 pre-industrial, historical, and future scenario simulations used in ISIMIP3b these variables are only available at monthly resolution, additional steps are necessary to generate climatological high-frequency fluxes first. In the following, we first describe these preparatory steps, and then the de-biasing strategy, in more detail.

949

950

951

952

953

954

955

956

957

958

**High-frequency surface flux forcing.** Initially, a climatological simulation spanning the historical period from 1958 to 2022 is performed by forcing the ocean model NEMO-PISCES with a single repeating annual cycle representative of the 1990s' climate conditions sourced from the "Repeat Year Forcing" (RYF) from JRA55 reanalysis (Stewart et al., 2020). This simulation is driven using the CORE bulk formulae (Large W. G., 2004), incorporating all surface atmospheric variables at 3-hourly resolution from JRA55 RYF as inputs and storing 3-hourly momentum, heat and freshwater fluxes from this simulation. These 3-hourly JRA55 RYF fluxes are added to the monthly seasonal flux anomalies available from the ISIMIP3b climate models for the pre-industrial (picontrol), historical (historical) and future SSP1-2.6 (ssp126), SSP3-7.0 (ssp370), and SSP5-8.5 (ssp585) scenarios. In this way, 3-hourly surface flux forcings are created for all

959 ISIMIP3b scenarios. Notably, this procedure results in sub-monthly variability mirroring that of the JRA55  
960 RYF, rather than the variability simulated by the coupled climate model. This means that any projected  
961 changes in sub-monthly variability due to climate change are not integrated in the final de-biased product.  
962 However, to date, marine ecosystem modellers have not analysed sub-monthly variability anyways (and  
963 most marine ecosystem models are not suited to account for sub-monthly variability of forcings), making  
964 this approach suitable.

965 Alternatively, de-biased ocean simulations including GCM-based sub-monthly variability could be  
966 constructed by an alternative approach. In this scenario, 3-hourly surface atmospheric variables would be  
967 extracted directly from each GCM simulation, rather than from JRA55 RYF forced oceanic simulations.  
968 Forcing NEMO-PISCES with these variables using bulk formulae would once again produce the necessary  
969 3-hourly surface fluxes, this time with variability consistent with the coupled GCM across all timescales.  
970 This approach however requires running a separate ocean simulation for each GCM and scenario to derive  
971 the surface fluxes, necessitating a much larger number of ocean model runs than the approach using  
972 JRA55 RYF. In addition, the 3-hourly input from the GCMs is not available without gaps.

973

974 **De-biasing strategy.** The 3-hourly surface fluxes, constructed as described above, then serve as forcings  
975 for another set of ocean model simulations. Notably, these simulations are not driven with bulk formulae  
976 but directly with surface fluxes to enable an online implementation of the surface heat flux feedbacks  
977 triggered by climate change into the forced ocean biogeochemistry model for historical and future  
978 simulations (Lengaigne et al., 2025). For bias-adjustment, the part of the anomalous surface fluxes that  
979 directly depends on climate change-induced SST warming is separated from the part that does not. Only  
980 the latter part is used as a direct flux input to the ocean model, while the former is implemented within  
981 NEMO-PISCES as an online relaxation to the warming signal from the debiased historical and future  
982 simulations using a spatially and seasonally variable feedback damping coefficient. This SST feedback  
983 coefficient, derived from observed surface variables, represents the Newtonian cooling negative feedback  
984 related to latent heat fluxes through the Clausius-Clapeyron relationship and the negative feedback  
985 related to upward long-wave radiation through Stefan's law (Zhang & Li, 2014) and the positive downward  
986 longwave radiation feedback related to increasing temperature (Shakespeare & Roderick, 2022).  
987 Application of this approach to the ocean model effectively reproduces the global SST changes simulated  
988 by CMIP6 models, as demonstrated in (Lengaigne et al., 2025).

989 In this way, physical and biogeochemical ocean simulations are generated for piconrol and historical  
990 climate forcings as well as for each of the future climate change scenarios, ensuring that the background  
991 climatological state is constrained by the reanalysis, while still accounting for both interannual and long-  
992 term climate variability simulated by the underlying GCM. Consequently, the resulting ocean-  
993 biogeochemistry simulations considerably mitigate the strong present-day climatological biases identified  
994 in the coupled models. Depending on data availability for the relevant monthly fluxes, this de-biasing  
995 procedure can be applied to any climate model.

996 Additionally, to generate observation-based oceanic forcings for ISIMIP3a, a reference simulation is also  
997 forced with the full JRA55 forcing (Tsujino et al., 2018) that includes observed inter-annual and decadal  
998 variability. This oceanic forcing is expected to be a valuable additional [CRFclimate-related forcing](#)  
999 for impact model evaluation within ISIMIP3a akin to the GFDL-MOM6-COBALT2 reanalysis-driven historical

1000 dataset used in ISIMIP3a (Frieler et al., 2024a). The set of variables included in the de-biased dataset is a  
 1001 subset to the one in the raw GCM dataset (**Table 8**), detailed in **Table 9**.

1002  
 1003 **Table 9:** Bias-adjusted ocean data to be used by global impact models in the ‘de-biased’ sensitivity  
 1004 experiment in the fisheries and marine ecosystems sector

1019

1020

Regional marine ecosystem models are most often calibrated to reproduce observed environmental variables when driven by observed sea surface and bottom temperature, primary production (phytoplankton production), and zooplankton biomass. However, that would still lead to biases in the historical simulations if the impact model was forced by biased simulated input data instead of observational data. To reduce this effect the GCM-based input data has been adjusted such that the historical GCM simulations match observational data for certain regions (Eddy et al., 2025). The adjustment is based on the delta approach where simulated and observational forcing data  $X_{sim}$  and  $X_{obs}$  are averaged across a given historical reference period to determine the bias  $\Delta = \text{mean}(X_{sim}) - \text{mean}(X_{obs})$  that is then subtracted from the simulated forcing data. This method preserves the trend in the forcing data and its internal variability. Some ocean forcing variables are not an exact match with variables used in regional marine ecosystem models. For example, sea water potential temperature ( $\theta_{\text{sea}}$ ), concentration of diatoms ( $\text{phydiat-vint}$ ), or concentration of mesozooplankton ( $\text{zmeso-vint}$ ) may first be converted to other indicators that are then used as input for the regional marine ecosystem models. In these cases the derived indicator is corrected using the delta method (see **Table 10**).

1021

**Table 10:** Bias-adjusted ocean data to be used by regional impact models in the 'de-biased' sensitivity experiment in the fisheries and marine ecosystems sector

1022

Variable	Variable specifier	Unit	Resolution	Forcing datasets
Southern Benguela Current				

Net primary organic carbon production by all types of phytoplankton	<b>intpp</b>	mol m <sup>-2</sup> s <sup>-1</sup>	1° grid, monthly	Corrected based on observed primary production for the southern Benguela current based on the delta method where the adjustment target is data from 1978 for the EwE model and 1990 for the Atlantis model
Sea water potential temperature	<b>thetao</b>	°C	1° grid, vertically resolved, monthly	Raw GCM temperature data converted to temperatures at 0-50, 50-100, 100-300 and 300-500 m according to the configuration for the southern Benguela Atlantis model, and 0-50 and 300-500 m for the EwE model.
Cook Strait				
Net primary organic carbon production by all types of phytoplankton	<b>intpp</b>	mol m <sup>-2</sup> s <sup>-1</sup>	1° grid, monthly	Corrected based on observed primary production for Cook Strait using the delta method where observational target data is from 1950
East Bass Strait				
Net primary organic carbon production by all types of phytoplankton	<b>intpp</b>	mol m <sup>-2</sup> s <sup>-1</sup>	1° grid, monthly	Corrected based on observed primary production for East Bass Strait using the delta method where observational target data is from 1994
East Bering Sea				
Concentration of diatoms expressed as carbon in sea water	<b>phydiat-vint</b>	mol m <sup>-3</sup>	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to phytoplankton size classes used in East Bering Sea mizer model then corrected using the delta method for the period 1982–1993
Concentration of diazotrophs expressed as carbon in sea water	<b>phydiaz-vint</b>	mol m <sup>-3</sup>	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to phytoplankton size classes used in East Bering Sea mizer model then corrected using the delta method for the period 1982–1993

Concentration of picoplankton expressed as carbon in sea water	<b>phypico-vint</b>	mol m-3	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to phytoplankton size classes used in East Bering Sea mizer model then corrected using the delta method for the period 1982–1993
Concentration of mesozooplankton expressed as carbon in sea water	<b>zmeso-vint</b>	mol m-3	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to zooplankton size classes used in East Bering Sea mizer model then corrected using the delta method for the period 1982–1993
Concentration of microzooplankton expressed as carbon in sea water	<b>zmicro-vint</b>	mol m-3	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to zooplankton size classes used in East Bering Sea mizer model then corrected using the delta method for the period 1982–1993
Sea surface temperature	<b>tos</b>	°C	1/4° grid, monthly	Corrected based on configuration for the East Bering Sea mizer model using the delta method for the period 1982–1993
Hawai'i				
Concentration of diatoms expressed as carbon in sea water	<b>phydiat-vint</b>	mol m-3	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to phytoplankton size classes used in Hawaii mizer model (Woodworth-Jefcoats, 2022) then corrected using the delta method
Concentration of diazotrophs expressed as carbon in sea water	<b>phydiaz-vint</b>	mol m-3	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to phytoplankton size classes used in Hawaii mizer model then corrected using the delta method
Concentration of picoplankton expressed as carbon in sea water	<b>phypico-vint</b>	mol m-3	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to phytoplankton size classes used in Hawaii mizer model then corrected using the delta method

Concentration of mesozooplankton expressed as carbon in sea water	<b>zmeso-vint</b>	mol m-3	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to zooplankton size classes used in Hawaii mizer model then corrected using the delta method
Concentration of microzooplankton expressed as carbon in sea water	<b>zmicro-vint</b>	mol m-3	1/4° grid, vertically resolved and vertically integrated, monthly	Converted to zooplankton size classes used in Hawaii mizer model then corrected using the delta method
Sea water potential temperature	<b>thetao</b>	°C	1/4° grid, vertically resolved, monthly	Converted to temperature used in Hawaii Mizer model then corrected based on observed sea water potential temperature for Hawaii using the delta method from 1961–1980 with observed temperature data from the World Ocean Atlas

1024

1025

## 2.5 Future Lightning Data

1026

1027

1028

1029

For the ‘varlighting’ sensitivity experiment we provide temporally varying lightning density (strokes km<sup>-2</sup> day<sup>-1</sup>) for the period 2015-2100 on monthly resolution (monthly mean of daily lightning stroke density) and the standard 0.5° global grid. This dataset may be used in a range of applications, for example, to understand the influence of lightning on wildfire ignition or atmospheric composition.

1030

1031

1032

1033

1034

The lightning density is derived from future climate simulations by UKESM1-0-LL and an empirical relationship between Convective Available Potential Energy (CAPE) and lightning strokes based on the WWLLN Global Lightning Climatology and time-series (WGLC) (Kaplan & Lau, 2021, 2022). Daily mean CAPE is calculated from non bias-adjusted air temperature, air pressure, and specific humidity on pressure levels from the surface to the top of the troposphere.

1035

1036

1037

1038

1039

The relationship between daily CAPE and daily lightning is estimated by linear regression of log-transformed CAPE derived from the GCM-calculated CAPE during the period of overlapping model output and observed daily lightning from WGLC (2015-2020) for each gridcell and month of the year. Where <10 observations of daily lightning were available over the calibration period, we used global mean regression parameters.

1040

1041

1042

The empirical relationships are applied to the daily CAPE data from the UKESM1-0-LL simulations for all three climate scenarios SSP1-2.6, SSP3-7.0, and SSP5-8.5. The associated lightning densities were monthly averaged. To maintain the spatial structure of lightning observed at present, lightning anomalies

1043 compared to the simulated 2015-2020 climatological reference were added to the observed present-day  
 1044 lightning climatology from WGLC for 2015-2020. The ‘varlightning’ sensitivity experiment is assumed to  
 1045 start from the default historical group I simulation, assuming the Flash Rate Monthly Climatology (Cecil,  
 1046 2006), not changing with climate change.

1047  
 1048  
 1049

**Table 11:** Future lightning forcing data provided within ISIMIP3b.

Variable	Variable specifier	Unit	Resolution	Datasets
Monthly flash rate	<b>lightning</b>	km-2 d-1	0.5° grid, monthly	Derived from UKESM1-0-LL (SSP1-2.6, SSP3-7.0, and SSP5-8.5) using an empirical relationship between Convective Available Potential Energy (CAPE) and lightning densities (Kaplan et al., 2023).

 1066  
 1067

This paper gives an overview over the ISIMIP3b, group I and II experiments and the provided climate-related forcing data sets. The simulations assuming fixed 2015 direct human forcings and a low (ssp126) and two high emission scenarios (ssp370 and ssp585) are designed to describe the impacts of different levels of climate change on present day natural and human systems. The set-up allows e.g. for testing to what degree the (bio-)physical impacts scale with global mean temperature change and could therefore be translated to other global warming pathways than the ones considered here. While a functional relationship between the considered impact indicator and global mean temperature change (or other climate variables) could be trained on ssp585 simulations because of the high warming levels reached, its performance could then be tested on ssp370 and ssp126. However, in such a setting it has to be taken into account that ssp370 is different from the other scenarios with regard to particularly high aerosol emissions and high decreases in forest areas going beyond the assumptions in the other models. So it has been shown that the increase of global mean precipitation with global warming is much weaker in SSP3-7.0 than in the other scenarios (Shiogama et al., 2023).

1068  
 1069  
 1070  
 1071  
 1072  
 1073  
 1074

This paper is intended to work as a catalogue where the climate impact modellers can find all relevant information about the climate-related forcings needed as reference for the impact model simulations generated within the CMIP6-based ISIMIP3b, group I (historical period) and group II (future projections). As a continuous process we would like to improve or complement these data sets wherever possible. So this paper can also be read as a call to either contribute by additional input data that allows other sectors to join the current simulation round or by methods that could be used to generate additional data sets

1075 for the next simulation round that will likely build on CMIP7 simulations. The following climate-related  
1076 forcings have been identified as still missing and particularly critical to be added to a fourth simulation  
1077 round of ISIMIP: i) temporally resolved lightning data accounting for changes in climate, ii) bias-adjusted  
1078 oceanic forcing data, iii) projected coastal water levels in high temporal resolution accounting for  
1079 extremes and representing the effects of long term sea level rise in line with the underlying global climate  
1080 simulations, and v) ozone concentration fields in line with the GCM simulations. While a bias-adjustment  
1081 of the oceanic forcings is already suggested in section 2.4.2, the approach does not preserve the daily  
1082 variability of the raw oceanic forcings as it requires atmospheric surface flux only available in monthly  
1083 resolution from the ISIMIP3b GCMs. To ensure the consistency on daily time scale, we have submitted an  
1084 associated request for CMIP7 whose simulations will be used within the next round of ISIMIP. The  
1085 generation of high resolution coastal water levels is ongoing research described in section 2.2.3. In  
1086 particular the generation of the short term variability that will have to be added to the long term trends  
1087 in water levels still has to be developed and prove to fulfill the demands. In addition, it would be great to  
1088 also provide estimates of the extreme coastal water levels associated with the tropical cyclone tracks and  
1089 wind fields we provide within ISIMIP3b (see section 2.2). There is a general demand for higher resolution  
1090 ~~CRFclimate-related forcings~~ including both, the oceanic and the atmospheric components ideally  
1091 accounting for heat island effects. As the ISIMIP ~~CRFclimate-related forcings~~ have to be globally consistent  
1092 in the sense that they have to represent the daily variability of the underlying coarse resolution GCMs, we  
1093 cannot use data from dynamical downscaling approaches using boundary conditions from different GCM  
1094 runs as for example available through CORDEX. However, it seems to be appealing to harmonize the  
1095 selection of the ISIMIP GCMs with a priority setting regarding the GCM-based boundary conditions within  
1096 CORDEX.

1097  
1098 The climate-related forcings described here are also provided as input for the new ISIMIP3b, group III  
1099 simulations where the associated Direct Human Forcings (DHF) are not held constant at 2015 levels but  
1100 are projected into the future in line with i) the population growth and economic development associated  
1101 with the considered Shared Socioeconomic Pathways (SSPs) and mitigation measures required to reach  
1102 the prescribed levels of climate forcings associated with the climate projections ('no adaptation'  
1103 experiments) and ii) additionally accounting for the impacts of climate change ('adaptation' experiments).  
1104 The collection of the associated DHF will be described in a separate paper.

1105  
1106 **Code and data availability.** -All generated ISIMIP3 climate-related forcing data described in this paper is  
1107 publicly available at the ISIMIP data repository The repository is hosted by the Potsdam Institute for  
1108 Climate Impact Research (PIK) e.V. which is part of the TIB DOI Consortium ensuring persistent, FAIR-  
1109 compliant data publication, by committing to adhering to the DataCite Consortium Agreement. This  
1110 includes commitments to data persistence (§4 a.) as well as maintaining and updating metadata (§4 c.),  
1111 which forbids “withdrawing content without posting a notification”. In compliance with these rules a  
1112 system to document and trace back data issues has been implemented in the repository to comply with  
1113 this requirement. Additionally, should PIK be unable to continue hosting the ISIMIP repository, it will take  
1114 responsibility for coordinating a timely transfer of the full repository and its DOI infrastructure to an  
1115 appropriate, trusted archive or institutional partner to ensure uninterrupted access and citation

1116 continuity. DOIs are used to refer to datasets in a persistent way. Whenever a dataset is replaced a copy  
1117 is kept on tape, and a new DOI is issued, while the old DOI is kept online with information on how to  
1118 retrieve the archived data. Whenever we need to replace datasets, we will create a new version of the  
1119 DOI, marked by a version number at the end. This ensures that every DOI references exactly the datasets,  
1120 which were public at the time of registration. Detailed information can be found in the ISIMIP terms of  
1121 use at <https://www.isimip.org/gettingstarted/terms-of-use/> (ISIMIP terms of use, 2023).

1122 ~~The MIT data on tropical cyclone tracks with wind and precipitation fields data shall be used for non-~~  
1123 ~~commercial research or academic purposes only. Data can be made available by the ISIMIP team upon~~  
1124 ~~written consent by Kerry Emanuel (MIT, email: [emanuel@mit.edu](mailto:emanuel@mit.edu)).~~

1125 ~~All other input data described are available for participating modelers with a respective account from the~~  
1126 ~~DKRZ server. Data will be made publicly available, and most data are already publicly available at the~~  
1127 ~~ISIMIP data repository at <https://data.isimip.org/> (ISIMIP data repository, 2025) and availability is~~  
1128 ~~documented in the ISIMIP Input data table [https://www.isimip.org/gettingstarted/input-data-bias-](https://www.isimip.org/gettingstarted/input-data-bias-adjustment/)~~  
1129 ~~adjustment/ (ISIMIP input data table, 2025) where the way to access the data is described as well. Model~~  
1130 ~~output is already partly available <https://data.isimip.org/> (ISIMIP data repository, 2025). The ISIMIP~~  
1131 ~~repository fulfills the archive standards as stated in the “GMD code and data policy”. The repository is~~  
1132 ~~hosted and maintained by the Potsdam Institute for Climate Impact Research (PIK). Data can only be~~  
1133 ~~published or removed from the repository by the ISIMIP data team, which is monitored by the ISIMIP~~  
1134 ~~steering committee according to the organizational structure of ISIMIP. DOIs are used to refer to datasets~~  
1135 ~~in a persistent way. Whenever a dataset is replaced for any reason a copy is kept on tape, and a new DOI~~  
1136 ~~is issued, while the old DOI is kept online with information on how to retrieve the archived data. Detailed~~  
1137 ~~information can be found in the ISIMIP terms of use at <https://www.isimip.org/gettingstarted/terms-of-use/>~~  
1138 ~~(ISIMIP terms of use, 2023).~~

#### 1140 **Author contributions**

1141 KF lead the project and developed the concept with contributions from JS, MM, CO, CPOR, SH, JLB, CSH,  
1142 CMP, TDE, KOC, CN, RH, DPT, OM, SJC, JJ, SR, GL, SC, EB, AGS, NS, JC, SH, CB, AG, FL, SNG, HMS, FH, TH,  
1143 RM, DP, WT, DMB, RL, AIA, MF, MB, RR, and IDG. JV, MB, JK, IDVDV, LN, IJS supported the quality control  
1144 and curation of the climate-related forcing data and the protocol development together with the sectoral  
1145 ISIMIP coordinators listed as co-authors. SL developed the method and generated the downscaled and  
1146 bias-adjusted atmospheric climate forcing data. MM and ST provided the description of the approach to  
1147 generate the coastal water level data. ML provided the description of the method to bias-adjust the global  
1148 oceanic forcings. TV, DQC, CYL, SJC, and KE provided TC data. JOK and AK provided the future lightning  
1149 data. KF prepared the manuscript with contributions from all co-authors.
